for the determination of policy, and also the education of public opinion

Mr McCallum's "Public Opinion and the Last Peace" contains no such constructive proposals, but his review of the changes in public opinion with regard to the problems arising out of the Treaty of Versailles and the way in which these contributed to the disaster of 1939, demonstrates once again the dangers of an uneducated public opinion and also of the absence of clear, straight thinking on the part of statesmen and party leaders. Once again it is apparent that courage and honesty are the foundations of effective policy, and there could scarcely be more emphatic evidence of the importance of some official effort to guide public opinion as to what is involved in public measures and policies than in these two books.

The *Planning* broadsheet drives home the same lesson, though from another point of view. The conception of government as a positive and not a merely negative function plays in this, as in other *Planning* broadsheets, an important part in leading up to the conclusions which are drawn: the Government cannot perform its larger functions in the social and economic life of the community unless it has the right and means to make its purposes and methods effectively known. That need cannot be wholly met by full reporting of Parliamentary debates, and it is high time, in consonance with democratic principle, that fuller and simpler explanations be given to the great majority of people, who have a right to know why and what their Government has done, is doing and wishes to do. Explanation cannot be left entirely to the initiative of newspapers and book publishers: the administration is entitled in the public interest to take its own view of what requires explanation and by what means the explanation can best be given. Equally it is important that Government should be kept continuously aware of the citizen's point of view.

The P E P Group which has produced "Government Information Services" has admirably fulfilled its set purpose of adding to public knowledge of this important aspect of government, evaluating criticism and drawing up recommendations for the future. The history of Government public relations departments is briefly reviewed, and the lucid analysis of current criticism and of future activities leads to proposals for their future scope and organization which are concisely summarized. While there is nothing very novel in these recommendations—the Group agrees on the whole with the view that the end of the War should see the end of the Ministry of Information—the need is emphasized for an early decision by the Government as to the way in which certain of the functions of the Ministry are to be perpetuated. Just how the centralized responsibility for public information should be discharged in peacetime may be a question to which the answer can best be found in practice. The broadsheet shows clearly that the function of Government information is not exhausted even in the adequate performance by administrative departments of their own functions.

The first P E P recommendation is that Government information services should continue after the War through departmental units. Their functions should include the provision of news and information about administrative activity and the background of policy, public instruction on appropriate themes, and advice to their Ministries on public attitudes and opinions. To avoid misunderstanding and to keep present to the minds of the officers themselves the essential nature and the proper limits of their task, the term 'public relations' should be dropped and 'information' substituted. To provide technical and creative services, P E P recommends that a central publicity unit should be set up, attached to the Treasury, the Lord President of the Council or the Cabinet Offices, and operating under the general direction of a standing committee of departmental directors of information services. The unit would take over the work of such divisions of the Ministry of Information as films, publications, photographs, exhibitions and campaigns, and be responsible for buying space, time and commodities for all Government advertising. In the production of publicity, departments should be free to deal direct with private agencies where these exist.

With regard to themes, it is suggested that, as before the War, information units should undertake publicity on such questions as health and road safety, and should also provide information about new post-war measures and policies. Fuller background information should be given on subjects of general interest such as foreign affairs and public finance. Food and works relations publicity should also continue, the latter under the joint sponsorship of Government, employers' organizations and the trade unions, with considerable devolution of control to the level of industries and factories. If the inherent dangers and difficulties can be overcome, information services in this field might do something materially to improve industrial relations and to promote the closer integration of industry with the community it serves. Furthermore, information services should cover the general nature and methods of the Civil Service and its work. A fuller and wider knowledge of the facts and reasons on the part of the public would both be a safeguard against bureaucracy and prejudiced criticism of the Civil Service and accelerate any necessary or desirable changes in the Service itself. The more light is thrown on the purposes and methods of Government departments, the less likely are obsolete techniques, sectional habits of thought and indifference to the service of the public to survive. Moreover, it cannot be doubted that if considerable changes in the machinery of government at any level prove necessary to serve our new needs, public understanding and consent will be indispensable before such changes can be implemented.

With regard to departmental arrangements, the broadsheet urges that the head of the departmental branch should have sufficient status to give him access to the Minister, and adequate authority in negotiation and conference, a rank of at least assistant secretary is proposed. While the size and

iversity of the staff must depend on the size and ork of the Ministry, in general large technical staffs could be avoided; a small highly-qualified staff able to use outside services, with a chief of high Civil service rank, is preferred. The director himself need not be a technician, but should be well qualified to direct and control the technical services involved. Initially, directors might be chosen from outside, sometimes on a temporary basis; but in due course these posts could be filled by Civil Servants with the right aptitudes and some experience in information branches.

The broadsheet also directs attention to the value of close links between information branches, departmental intelligence units and libraries. In the Ministry of Health, these have from their inception been organically related, but in other Ministries relations are casual, and there may be no functional or administrative relation between public relations and the library, the statistical branch and the intelligence branch or any of them. Indeed the broadsheet goes so far as to suggest that if Whitehall had before the War been staffed with public relations branches which knew their business, the neglect of statistics and research which marred the administrative work of some Departments of State might in part have been corrected. At this point some clear thinking will obviously be required if the proposals are not to conflict with those which have been advanced by the Council of the Royal Statistical Society in its memorandum on official statistics and which, as the Prime Minister has announced, are now to be discussed with representatives of the departments concerned at a special meeting.

Another subject which calls for further consideration is the provision of information about public opinion. The first and most important source of such information is Parliament, but the Parliamentary interpretation of public opinion needs to be supplemented, as it has been during the War, by scientific surveys of public opinion. This need may arise from administrative considerations—the Requisitioned Land and War Works Bill is a glaring instance of the consequences of administrative neglect in this respect—and while these needs may sometimes be served by limited *ad hoc* inquiries, there is little doubt that more elaborate and fundamental researches may sometimes be required.

The broadsheet is emphatic that the Government should not be deprived of the use of scientific research in this field, but is hesitant as to the method and safeguards. The results of such studies should be published, though delay might sometimes be desirable. Tentatively, it is suggested that the right answer might be to encourage the formation of a social research council or institute under the aegis of the Lord President, financed by the State, but with independent scientific status. Such a body might align itself with the work of the universities and private agencies in this field and could take charge of the official research unit. The broadsheet rightly points out that the public opinion survey represents a new and important method of investigation in the social sciences, of which

the Government should not be wholly deprived; this should be sufficient answer to criticism about interference with civil liberties and spying into private affairs which have been made.

Local information services are important and should be remembered in connexion with the training of local staffs of central departments. The work of the Citizens' Advice Bureaux and the war-time local information centres should continue, the latter should cover the whole province of local government and should keep in touch with the local offices of the Government. Some regional co-ordination by the central Government of its own local information activities will probably be necessary, and the machinery for this could be attached to the central publicity unit.

Finally, reviewing the safeguards against the abuses to which Government information services might be subject, such as their use to press a Government case unduly against opposition, to give unfair advantage to a political party in power, to build up the personal reputations of Ministers, and to overweight the position of the executive *vis-à-vis* Parliament, the broadsheet points to the remedies in due publicity for the nature and operations of the information services themselves, the maintenance of proper codes and standards of conduct among the information staffs, responsible use of them by Ministers, and continuous vigilance by Parliament and the Press.

The careful examination of these dangers and safeguards in the broadsheets does not warrant pessimism as to their adequacy. Vigilance undoubtedly will be required, but an independent central publicity unit as suggested may be free from some of the dangers of departmentalism and be competent to make its contribution in that important field of policy-making which increasingly calls for the work of committees of Ministers dealing with wide general spheres. This is the reason for the suggestion that the standing committee of public relations or information officers should meet under the auspices of the Cabinet Office with a secretary provided by that Office, and that the central publicity unit should be similarly affiliated. Whether or not such developments in the direction of a Civil general staff come soon or late—for there is little doubt they will come—there can be no question that Government information services rightly organized and wisely handled have an important if not an indispensable part to play in the establishment of right relations between knowledge and power, the application of scientific and technical knowledge to public policy, the elimination of prejudice and passion and the harmonization of executive action and public opinion. Scientific workers who study this lucid broadsheet, with Lord Woolton's observations at the recent British Association Conference in mind, can scarcely miss the implications it holds for one of the central problems of to-day, namely, the question as to how best the results of scientific inquiry can be translated into public policy for the general welfare of the community.

INDIVIDUALITY IN HIGHER ORGANISMS

The Biological Basis of Individuality

By Prof Leo Loeb Pp xii+711 (Springfield, Ill., and Baltimore, Md. Charles C Thomas, London Baulière, Tindall and Cox, 1945) 10 50 dollars

THE origin and scope of this book are perhaps best indicated by the following paragraphs from the preface "The starting point of this analysis was a series of investigations on the transplantation of normal and tumour tissues which the author and his collaborators have carried out in the course of about forty-eight years, some of which, especially those dealing with inbred strains of mice, have not yet been published To make possible a unified account and interpretation of the various aspects of individuality, it was necessary for one person to undertake this work, rather than to edit a collective book written by specialists in the different sciences which contribute the data needed for this purpose The method thus chosen suffers from the difficulty that a single author may not be able to treat with equal competence the problems involved, but it is believed that the unified presentation of these fields may, to a certain extent, compensate for such a deficiency

"In the following chapters these types of individuality are analysed as to their evolution and their biological and physical manifestations

"It is hoped that this presentation may be of interest to the biologist and to the general pathologist and that certain parts of it may be helpful even to the surgeon in the practice of tissue grafting, to the geneticist, to the student of cancer and to the immunologist, perhaps also to the psychologist and to some philosophers"

There is, however, much more in the book than might be gathered from these introductory remarks as it is, in fact, a serious and lengthy treatise on the whole subject, including its history and later developments These are gone into in very considerable detail and a valuable bibliography, brought up to 1943, of some eleven hundred and fifty books and papers is appended

Within the limits of a short review it is obviously not possible to give more than a general idea of a work of this size, but some points may be noticed

In the first place, as the term 'individuality differential' and other 'differentials' are constantly used throughout the book and, as the sense in which they are used by the author may not be immediately apparent to the reader of this review, a few words on their meaning may not be out of place It is now known that there is inherent in every higher individual organism something differentiating it from every other individual, which can be discovered by observing the reactions of certain cells and tissues belonging to one individual towards the tissues and cells of another individual of the same species This particular characteristic the author names the 'individuality differential', which is common to all (or almost all) the various tissues and organs of the individual In the same way there are species-, genus-, order-, class-differentials which, together with the individuality differentials, he designates as 'organismal differentials', among which the individuality differential is the highest and finest one

There are two principal methods by which the organismal differentials in general can be analysed (1) by various types of transplantation, and (2) by

serological methods The author and his collaborators have concerned themselves principally with the former method, which he regards as best suited for the investigation of the individuality differential A very large number of transplantations of various tissues into different animals are described and discussed in detail The subjects dealt with in this way include autogenous and homoogenous transplantations in various species, the individuality differential of closely inbred animals, the problems and criteria of success or failure in transplantation of tissues and organs, transplantation of tissues into the allantois (chick embryos, into the brain or into the anterior chamber of the eye The local and general reaction of the host to the transplanted tissues have also been investigated and critically discussed

Interesting chapters deal with the phylogenetic and ontogenetic development of individuality, and with transplantation and individuality in certain invertebrates and lower vertebrates

Another section of the book is concerned with the nature of tumours, with a comparison between the results of the transplantation of tumours and of normal tissues The influence of heredity and of immunity on the results of such transplantations are also discussed

In evaluating the results of transplantation experiments for the analysis of the individuality differential, the author classified these into six grades according to the degree of reaction provoked in the host by the graft and, while admitting that the method can claim only approximate exactitude, he regards it as still very helpful in comparing the results obtained if different types of individuality differentials are made to interact

As regards serological methods, although these have not engaged the practical attention of the author to the same extent as transplantation, they are very fully dealt with in chapters on the blood groups and heterogenetic antigens, the differentiation of individuality differentials by serological methods, idiosyncrasy and anaphylaxis, and the chemical nature of organismal differentials, etc

There is one point on which the reviewer cannot see eye to eye with the author He says that, "While the serological tests are especially useful in the analysis of the differentials of groups of animals, such as species, genera, orders, and classes, transplantation experiments are best suited for the analysis of the differences between individuals as expressed in their individuality differentials" (p 6), and that "serological tests are only under very restricted conditions serviceable in the detection of finer differences" (p 8). Up to the end of last century this may have been the case, but the discovery of the isolyms by Ehrlich and Morgenroth in 1900, by eliminating species and similar complicating factors, enabled attention to be concentrated on the finer differences, and later work showed that, at any rate in certain species (for example, cattle and fowls), it is possible by means of comparatively simple serological reactions to identify with ease and certainty any one individual out of a large group of individuals of the same species, provided that none of these is closely related, thus demonstrating the extraordinarily delicate nature of these reactions The objection, that only one kind of cell (the red blood corpuscle) is used, is met by the definition of the individuality differential which postulates the presence of this differential in all, or almost all, the cells and tissues of the individual

A perusal of the very full and interesting chapter on the chemical nature of organismal differentials will probably convince most readers that future advances in the subject are to be looked for as the result of the efforts of serologists and chemists working in collaboration.

The author concludes with several chapters on more general aspects of the subject, dealing with psychical-social individuality, individuality and the world, and the evolution of individuality. These, however, come more within the sphere of philosophy and are outside the competency of the reviewer.

This book, which embodies the life-work and thought of its author, and includes a critical and almost encyclopædic account of the work of others, will be invaluable to all workers on the subject of individuality and, in view of the wide field covered, will greatly interest many of those working on allied subjects, as suggested in the preface.

C TODD

STIMULATING INDUSTRIAL ENTERPRISE

Refrigeration in the Engineering Industry

Pp. xi+69 (typescript) (London: O. W. Roskill and Co. (Reports), Ltd., 1945) 42s

IT is generally agreed that in the industrial organization which will follow the War it will be necessary for each manufacturer to take full advantage of any technological advances which may be applicable to his particular work. The object of the present report is to help manufacturers of refrigerating plant by pointing out to them some of the fields in which refrigeration can be applied, and conversely to help those engaged in industrial processes where refrigeration would be helpful.

The first suggestion which is offered relates to the maintenance of upper-air conditions in rooms where tests or development of aeronautical instruments, engines or components may be carried out. Here, it is evident that no one wishing to test such appliances under conditions approximating to those which they will meet in service would overlook the need for refrigeration, though it is possible that refrigerating engineers might overlook the special needs, and the potential market, of this application. What the report does is to describe, in not very great detail, the installations which have already been set up for this purpose.

Another application is to the age-hardening alloys. As is well known, after heat treatment, these alloys alter in constitution at temperatures so low as ordinary room-temperature, in many cases it is essential to use them before the age-hardening has taken place, which often means, within two hours of the heat treatment. Now, by storing them at really low temperature, the age-hardening can be delayed, so that it becomes possible to store the articles for periods of the order of a week. The obvious gain to a manufacturer, who needs, say, a stock of rivets, is immense, if he is relieved of the necessity of matching the supply always to the demand.

There is another metallurgical field in which refrigeration may be of use, namely, in the ageing of iron and steel castings, either by removal of mechanical stresses or by accelerating the changes in constitution which occur when the metal is cooled.

There is some divergence of practice in this subject, and the conclusions reached by several workers are outlined in the report. It is noticeable that all the descriptions and references are taken from the work of practical engineers, that of physicists and the more academic metallurgists being ignored. It is probable that more careful consideration of their results and conclusions would either reconcile or explain the divergences of practice mentioned.

The older method of making a shrink fit is to heat the member which is too small until it just fits the other, obviously, where the one that is too large is more easily manipulated, refrigeration can help by providing means of cooling this member until it fits the smaller. Examples of this method are given, and will no doubt suggest other cases to enterprising readers.

This part of the report closes with an account of the attempts which have been made to apply local cooling to welding-electrodes, and of other miscellaneous applications, one of which (the desiccation of air supplied to furnaces) is simply a special application of the problem of air-conditioning, an art which refrigeration engineers have certainly not neglected in the past few years.

The second part of the report reviews refrigeration plants themselves, mentioning what has been done to produce multi-stage machines and to make absorption and cold-air machines practicable. Its value will therefore be mainly to the manufacturer, and less to the purchaser or prospective purchaser of a plant, though the latter may benefit by having this conspectus of types available, and may be enabled to put his inquiries direct to a firm specializing in the kind of machine best suited to his problems.

From this account, it will be seen that the report, while offering suggestions for new work or methods of working, to manufacturers and others, does not make new, original suggestions, but simply displays for consideration the more novel processes or devices already used and described. Clearly this is a legitimate activity for business consultants to engage in, and it is apparently found to be useful, for this is at least the fourth report published by the same firm. At the same time, if these reports are useful, the question presents itself whether a much larger series, covering indeed all the main branches of technology, may be needed, and whether it would be better undertaken as a definite series under the guidance of some such body as one of the engineering institutions.

Chemists already have reviews of this sort, one for pure chemistry and one for applied, while physicists have the "Progress Reports" and the (American) *Physical Reviews*. All these publications find a ready sale, and it is at least possible that similar reviews, in which an engineer engaged in one part of the industry might rapidly survey the advances in other parts, would be equally valuable. Another means by which engineers could be kept in touch with advances in regions other than their own would be an abstract journal, but experience seems to show that engineers are not attracted by these.

If either a journal of reviews or one of abstracts is desirable, it is clearly for engineers to say which they want, how detailed the reviews should be, and how the journal should be directed. It is to be hoped that some responsible body will take up this inquiry. Meanwhile, reports such as the one under review will help to show what could be done.

J. H. AWBERRY.

NAMING OF THE REDWOODS

By PROF J DOYLE

University College, Dublin

A GENERIC segregation of the two redwoods has recently been proposed by Buchholz¹ on grounds to be referred to later. The coast redwood, with obvious priority claim to the name *Sequoia*, remains *Sequoia sempervirens*. A new generic name *Sequoiadendron* has been proposed for the Sierra redwood, long known as *Sequoia gigantea*. Buchholz¹ rejects the possible use of *Wellingtonia* as it was earlier used, though afterwards discarded, for one of the Sabiaceae and is thus a later homonym. In a later paper Looby and Doyle² expressed a general agreement with the advisability of a segregation, though they were not attracted by the choice of the new generic title. Now in many quarters, especially in California, a body of opinion objects to any change in the name of the Sierra redwood, desiring the retention of *Sequoia gigantea*. In a discussion of this subject in *Science*, Jones³ quotes extensively from this paper by Looby and Doyle as scientific support for the necessity of a segregation and refers to the authors as botanists "who, presumably, may be safely considered free from any motives ulterior to the spirit of scientific enquiry." Having been thus dragged, as it were, on the arbitration board dealing with this vexed question, a further personal statement may be permitted.

This question of the generic segregation of the Sequoias has been in mind for a long time. It was discussed, for example, with Dr Florin of Stockholm when he visited Ireland in 1938, but at that time the evidence did not seem convincing. It is now definitely and strongly felt that this earlier conservative view was the sounder, that the later agreement with the idea of segregation was a hasty judgment and that the Sierra redwood should retain the name *Sequoia gigantea*.

Dayton⁴ has reported the results of a questionnaire sent to a number of Californian botanists and foresters asking for their views on this matter. It is clear that a large majority wish to retain the old name. The objections raised, in most cases, have not, apparently, a strictly scientific basis. They amount rather to the raising of a slogan "Hands off the Redwoods", or an appeal to the Save the Redwoods League. Is the Sequoia National Park to change its name? If there are in future to be no Sequoias in that happy Eden, must it now be called the Sequoiadendron National Park? Such an approach to this question may appear unscientific, nevertheless such objections have a force and a vivid claim to sympathetic consideration from all to whom a tree, and especially a redwood, is something more than a mere name in a catalogue. For these redwoods are not ordinary trees. They are among the world's wonders. They are the possession, not only of professional botanists, but of also every forester and of every tree-lover. It is easy to appreciate the feelings of so many, who, regarding them with reverence and awe, shrink from subjecting them to the cold pedantic analysis of scientific botanists. The point is that, from the replies to Dayton's questionnaire, there is shown to exist a strong human emotional background against which the naming of these trees must be viewed. The evidence forcing a change of name must, therefore, be very cogent, and it is the purpose of this short article to submit that there is no such cogency. On the contrary, even apart from this background, even if the Sequoias were little-known,

plants, familiar to only a few specialists, it is hoped to show that generic segregation, on the basis of the evidence advanced, would be, at least among the conifers, a case of unnecessary splitting.

It may be recalled that Looby and Doyle⁵, having emended Lawson's⁶ early account of development in *Sequoia sempervirens*, first showed that the proembryo in *Sequoia gigantea* differed from that in the coast redwood. Buchholz⁷ afterwards described differences between them in the early embryogeny and followed this shortly by his formal proposal¹ for a generic segregation. In a later paper Looby and Doyle² further described many differences in the earlier stages from gynospore to fertilization. This is the paper from which Jones³ has quoted, and in which a general agreement, now withdrawn, was expressed with the idea of segregation. It is at any rate clear, without delaying on specific illustrations, that, from gynospore to early embryo, there are many differences in development in the two species.

Now the segregation as proposed by Buchholz¹ is, in fact, formally based on certain external features, on six of which special emphasis is laid. But in this paper Buchholz lists also a series of differences between the two under thirty-three headings. Sixteen of these are gametophytic or embryological. Further, certain of the headings are emphasized in italics and each of these is claimed to be of generic significance. Of such items only six are external features, but ten are features of development. Clearly, although not included in the formal diagnoses, these developmental differences must have considerably influenced Buchholz in proposing the segregation. "These weigh heavily," he says, "in confirming the conclusion that we are concerned here with two distinct genera." I was certainly influenced at the time by these developmental differences, and by these alone.

A little further consideration, however, shows that the use of gametophytic and embryological features as points of generic significance cannot be readily accepted. Obviously such features can seldom, if ever, be employed in the discrimination of fossil genera and, to be of value among living forms, their application to the conifers as a whole must be considered—their significance cannot be limited to the Sequoias alone. If so applied, and if differences are significant, are similarities to be significant or are such features to be used or ignored at will? Thus, almost all the stages in development, from gynospore to early embryogeny, are similar in *Savagothaea* and *Podocarpus andinus*, some being all but indistinguishable even in detail. On the other hand, most stages in *Podocarpus andinus* differ from those in *Podocarpus nivalis*. Developmental phases in species of *Phyllocladus* and *Dacrydium* also resemble those in *Savagothaea* and all, at least up to the early post-fertilization stage, show some remarkable similarities with *Pinus* and *Araucaria* (cf. Looby and Doyle⁸). What is the generic significance of such facts as these? There are intergrades in living *Podocarpus* species, between the developmental type of *Podocarpus andinus* and that of *P. nivalis*, but, if *Podocarpus* to-day were only represented by two extreme types, what would the position be? It surely is that gametophytic and embryological features may be of great value in assessing broad relationships and developmental lines within groups, large or small, but their generic significance is doubtful and indefinite.

The differences in development which, in fact, exist between the two redwoods may be related to another feature listed but not emphasized by Buch-

^z Although the chromosome numbers have not been exactly counted, it is clear enough that *Sequoia gigantea* is a normal diploid conifer type with $n = 11$ or 12 , while *Sequoia sempervirens* is a raploid with $n = 22$ or 24 . Tetraploidy is rare in the conifers, being only known to occur elsewhere, according to Sax and Sax⁹, in one rather rare garden variety—*Pfitzeriana*—of *Juniperus chinensis* and probably also in *Pseudolarix*. There may be features in the genetic and chromosomal balance of the order unfavourable to tetraploidy. Certainly the constitution of *sempervirens* itself seems to be somewhat unstable, as shown, for example, by the great vegetative variability and by the extreme condition of seed abortion which occurs. Commercial samples, collected from natural habitats, may show only 3 per cent of good seed. A strong tendency to sterility appears also at the stages of gametophytic and embryological development, at least under Irish conditions, and considerable variations, amounting to abnormalities, occur frequently at certain phases. It is suggested, therefore, at the gametophytic and embryological features shown by the coast redwood are developments induced by the tetraploid condition and that the species is best considered as a somewhat sterile, unstable and slightly aberrant derivative from a basal ploid *Sequoia* type now represented by *S. gigantea*. It is unlikely in an angiospermic genus that a generic segregation would be proposed if a tetraploid species showed some peculiarities in development.

Since developmental features seem little suited for use as generic characters, segregation must be based on external features and, in fact, it is on such features that Buchholz¹ has been forced to make his formal distinction. There is, however, nothing new in the list of external differences drawn up by him. The features cited have long been familiar to systematists such as Torrey, Masters, and Pilger, and differences which failed to impress them cannot be blatantly different. Many of these differences are obviously of minor importance. A long list of such could be drawn up between any two species, the length of the list depending merely on the patience of the observer. Points such as variations in wood density, in habit, or in bark appearance can be readily paralleled in any large genus such as *Pinus*. It is not proposed to go over, *seriatim*, all the minor points listed by Buchholz. Reference here can be limited, and then as briefly as possible, to some of the features which he lists as of greatest generic significance and on which his distinction is essentially based.

(1) Buchholz emphasizes that the Sierra redwood requires two seasons to ripen the embryo and seed while the coast redwood requires only one. This, however, is merely another example of a widespread phenomenon in conifers. Forms closer to the basal type show frequently a longer cycle, derivatives and more advanced forms a shorter cycle, and this may be shown within the family or within the genus. Thus within the family Pinaceae *Pinus* retains a longer, while *Pseudotsuga* shows the shorter cycle, but within each of the genera, *Podocarpus*, *Dacrydium* and *Araucaria*, as examples, the same phenomenon occurs.

(2) Difference in form of the cone scales in the two species is emphasized. But the difference is, in fact, slight. It is much less than exists between many species of *Pinus*. It is a great deal less than exists between, say, *Athrotaxis selaginoides* and *A. cupressoides*. These, however, are linked by *A. lasifolia*, the scales of which are nicely intermediate between the other two. If this species did not exist, a stronger claim

could be made for the generic segregation of the first two on the basis of cone scale difference than can be made for the two *Sequoias*. It is of particular interest in this connexion to recall that Chandler¹⁰, in a revision of *Sequoites Couttsiae*, describes considerable variation in cone scale form. The same specimen may show thin imbricate scales, strongly peltate scales and many intergrades. Thus this well-known fossil type may show, in one specimen, greater differences in scale form than those which are claimed to be of generic importance in the living types. Further, even a small collection shows some variation in cone scale form in both the living redwoods. It is therefore worth while noting, in view of the great variability shown by *S. sempervirens* in its foliage, that it is not clear whether the slight difference in cone scale form is in fact constant over a wide range of types and habitat.

(3) The ovules and, later, the seeds are stated to be more numerous and in a double row in *S. gigantea*, but fewer and in a single row in *S. sempervirens*. But even Buchholz¹ himself states that this is not constant. He gives 3–7 as the ovule number in the latter species and 3–12 in the former. What then of forms with 5 or 6? A few minutes' dissection of young cones shows, in any event, that scales of *S. gigantea* with 5 or 6 ovules may show no doubling, while in scales of *S. sempervirens* with 6 or 7, some of the ovules are commonly out of place, forming an incomplete second row. Buchholz further gives the seed number as 2–5 in a single row for *S. sempervirens* and 3–9 in a double or single row for *S. gigantea*. It is difficult to see how a character which may show such wide variation and such a degree of overlapping can be used as a generic character.

(4) The foliage differences, including the leaf dimorphism of *S. sempervirens*, are emphasized. But it is surely common knowledge that much wider foliage differences are tolerated in other genera, *Podocarpus*, for example. If it be objected that the present *Podocarpus* should be split into a number of separate genera, must we then generically segregate *Araucaria Bidwillii* and *A. balansae*? The foliage difference between these is wider than that between the *Sequoias*. And what of the junipers? Buchholz refers to the foliage of *S. gigantea* as "juniperoid". It is not clear, however, what is meant by that term as there are to be seen, in *Juniperus*, flat linear leaves with an abrupt peg-like base recalling the spruces, similar leaves with a green decurrent base, smaller acicular leaves close to the stem, closely adpressed cupressoid leaves and a whole series of intermediate types—the extremes much wider apart than in the *Sequoias*.

In regard to leaf dimorphism, it is again common knowledge that many conifer genera include species with only one leaf form and species showing leaf dimorphism of various types. This is well shown by the podocarps and araucarians. Thus *Araucaria Bidwillii* shows dimorphism, but the foliage of *A. araucana* is practically uniform. *Podocarpus* and *Dacrydium* both include species with only taxoid or only cupressoid foliage and species showing varying degrees of dimorphism. Thus *Dacrydium Kareri* may carry, on the same branch, flat taxoid leaves up to $1\frac{1}{2}$ in long and densely imbricate cupressoid leaves averaging only $1/10$ in, and the transition is abrupt. Other species of *Dacrydium* are less spectacular, but these dimorphic types are not generically segregated on that basis, rather they help to link up the purely cupressoid and purely taxoid types. *Podocarpus dactyloides* also bears cupressoid and taxoid foliage,

the two types grading somewhat. The taxoid type is essentially juvenile, but considerable foliage mixture occurs on older branches. Specimens may, however, retain completely the taxoid foliage for periods up to a hundred years, dependent on habitat and environment, so that full-grown coning examples of the same species in the same locality may appear very different and at least as distinct as the two Sequoias.

The occurrence, in *S. sempervirens*, of branchlets of a giganteoid type and the fact that some specimens, especially on freely coning branches, may carry almost as much giganteoid as taxoid foliage suggest, then, that the leaf dimorphism can be considered a linking rather than a separating character. This is not the place to survey fully the vegetative features of the coast redwood, but one further comment may be made. Possibly in relation to a polyploid instability it is one of the most variable of conifers. No one specimen can possibly be selected as the type. It would need many herbarium sheets to illustrate the manifold variations which may quite commonly occur. It is then remarkable that Buchholz¹ lists as typical characters of generic importance features of the taxoid leaves which are not to be found in any living material here available and which are not recorded in any of the better-known descriptions and drawings. The leaves are said to be scythe-shaped and petioled with prominent midrib and revolute margins. If these features do occur on fresh material and were not described from dried specimens only, they cannot be characters of the type, but serve merely to extend the range of variability within the species.

(5) The buds of *S. sempervirens* are said to be scaly and those of *S. gigantea* naked. The meaning of the term 'scaly' is not quite clear, as it is obvious in winter that the dormant terminal apices of *S. sempervirens* are not covered with highly specialized bud-scales like a spruce or a fir. Anyone not familiar with the redwoods, however, could easily get the impression from this statement by Buchholz¹, and from others in the literature, that the 'buds' of *S. sempervirens* are rather specialized structures and quite different from those of *S. gigantea*, whereas, in fact, the basal structure of the apices of branchlets and twigs is essentially the same in both. As the commonly available accounts are rather inadequate, this point needs, unfortunately, more lengthy comment than the others.

A certain common plan of construction can be seen in many conifers—*Cryptomeria*, *Cunninghamia*, species of *Araucaria* and many others. Irrespective of the type of foliage, a number of the leaves at the end of a current twig in winter can be seen to be smaller, closely imbricate, and commonly of a modified and reduced form. The most terminal, which may be slightly more modified though grading into those behind, cluster closely round and protect the dormant apical meristem and the young leaves of the next season already organized by it. These outer protecting leaves themselves grade into the inner protected ones, the whole is thus a simple bud. We have here just a cessation of growth with protection given by the last-formed modified leaves of the previous year. On resumption of extension growth in spring the group of small terminal leaves is left behind as a special zone at the base of the elongating twig, and these zones, scattered along the branches, indicate the sites of the winter rest. Their distinctness depends on the relative size of the adult leaves. In *Araucaria Bidwillii* longer zones of linear pectinate leaves alternate with the shorter clustered zones, while in

Cryptomeria and many of the small-leaved species *Araucaria*, in view of the more compact foliage, the sites of the winter rest are less obvious or even or to be found by close scrutiny. In cupressoid form the distinction scarcely exists.

The Sequoias show a similar plan and similar differences. The contrast between the zones of linear pectinate leaves and short imbricated ones is commonly very obvious in *S. sempervirens*, whereas close scrutiny is needed to locate the sites of winter rest in *S. gigantea*. Incidentally, since the coast redwood shows such great vegetative variability there occur also, as might be expected, variations in bud organization. It would take a long descriptive account to explain adequately the nature of these and this is not the place to deal with them. Suffice it to say that such variations are slight or rare or main affect bud location. Typically, however, the structure of the terminal apices is essentially similar in both Sequoias and quite in accordance with the plan outlined above, so that it cannot be said that one shows scaly buds, in winter in the open, and the other does not. Of course, there may be differences, often marked differences (in detail), identical can scarcely be expected in two very distinct species. But often, as in the frequent case in *S. sempervirens* of short lateral branchlets closely covered with densely imbricate reduced leaves, the structure of the apex, as well as the appearance of the whole branchlet, may be so strikingly similar to corresponding branchlets of *S. gigantea* that careless scrutiny could confuse small detached specimens.

The coast redwood, however, shows the peculiarity which has probably earned for it the reputation of having 'scaly' buds. The terminal group of small modified leaves, left behind on the resumption of extension growth in spring, may gradually wither and become brown so that the base of each branchlet may be encircled with a cluster of thick brown leathery scales. A few points in connexion with these are of interest. The withering and browning, in the first place, are gradual—a matter of weeks or months. In the second place, though common, they are not necessary or constant. Examination of almost any specimen will show cases, often quite frequently, in which some or all of these modified terminal leaves remain permanently green. Further, the browning is not limited to the most terminal of these leaves, those that cluster immediately round the resting meristem and which might be considered bud scales proper. Those back along the stem, for a distance which is usually short, but which may extend to as much as an inch, turn brown also. It would appear that a certain number of the last-formed modified leaves of the previous growth, those fairly matured, exposed, and attached to a stem zone which will not elongate in spring, may turn brown. Those not matured in the previous growth, protected by the outer older ones, and attached to a stem zone which will show extension, expand as foliage leaves. Needless to say, the delimitation is not absolutely sharp and many intermediate stages may be seen in spring.

Thus it is not a question of one type having 'scaly' buds and the other 'naked' buds. In both we are dealing with similar buds of a simple construction and of a relatively common type. The point is merely that in *S. sempervirens* a number of the terminal modified leaves of the previous growth may or may not turn brown in the course of the succeeding season. This unstable feature scarcely seems sufficient weighty to necessitate a generic segregation, especial

within *Juniperus*, *Podocarpus* and *Dacrydium*, relation to their wide variation in foliage type, a much wider range of differences can be met with in structure and behaviour of branch apices. Any one with access to a collection of junipers, to take one case, will find species with well-organized buds protected by definite and distinct bud-scales which may be deciduous, species with a later browning, like that of *S. sempervirens*, species that behave like *Metasequoia* or *Araucaria Bidwillii*, species with only a slight difference in foliage around the sites of immaturity, species showing a cupressoid habit with a distinct break between successive years' growth, and many intergrades. If the intergrading species disappeared and if *Juniperus* was now represented only by *J. oxycedrus* and *J. virginiana*, these, on the basis of leaf habit and bud type, would have a greater claim to generic segregation than the two Sequoias. Unfortunately, however, the intergrades do exist. Clearly, one of the many phases of vegetative development shown in *Juniperus* is the organization of fairly specialized buds. To anticipate comment may be mentioned that some of the *S. sempervirens* variation types show a tendency in this direction, though this appears to be rare. Young shoots, however, arising after felling, show the simpler type of bud.

(6) Buchholz¹ also states, and considers it important, that in the coast redwood the cone matures, grows and sheds seed within the year, while, in the Sierra redwood, the cone remains, for a number of years, green, attached to the tree and retaining its seeds. Actually the difference between them is less than would appear from this statement, there is a difference of degree only and not of kind. In *S. sempervirens*, at least under Irish conditions, the cones begin obvious growth from the bud in November, the matured cones shedding their seed late in December of the following year or even not until January of the next year still. Thus from onset of growth to shedding of seed may take up to fifteen months, after which the cones remain attached to the tree for a further couple of years. In *S. gigantea* visible growth from the bud begins in March, and the cones open to shed the seed any time after the third succeeding December, full maturing being thus spread over from $\frac{3}{4}$ to about 4 years. During this period they gradually darken and harden. But at any time after the maturing of the seed, late in the second autumn of growth or example, cones, brought indoors and kept dry and warm (60° F or less), will open the scales and become brown within about ten days. Maturing cones of *S. sempervirens*, brought indoors about the same time while still dark green and closed, take, surprisingly, nearly as long to brown and open. The physiological difference between the two does not seem considerable. It would be of interest to relate the behaviour of the two redwoods to their very different ecological habitats and to determine, under natural conditions, the actual factors controlling the shedding of seed in relation to the age of the cone and the like. It is suggested, however, that the important point in the cone behaviour of the two species is probably the ecological one of the longer seed retention by *S. gigantea* and that the slowness of the changes in its cone advancing to maturity, changes which can be so hastened by drying, are physiologically related to this. Whatever its biological interest, however, the behaviour difference seems generically a minor point, comparable to the fact that, in many of the larger genera, the leaves may

persist on the stem for greatly varying periods. But even if the difference were more fundamental than it appears to be, the relatively longer retention of seed by *S. gigantea* is, in any case, paralleled elsewhere in the conifers and the point not given generic significance. Such a retention is well known to be characteristic of many species of *Pinus* and is also seen in species of *Cupressus*, *C. torulosa* shedding both seeds and cones at seed maturity while *C. macrocarpa* may retain the seed for years, its cones gradually darkening and hardening.

In addition to these comments on six of the features most heavily emphasized by Buchholz¹, a few words are necessary on a very important consideration not referred to by him. If this generic segregation be made between the two living types, what then is to be done with the fossil nomenclature? What meaning in future must be given to *Sequoiites*? Or must there be two fossil genera *Sequoiites* and *Sequoiadendronites*? And how are the known fossils to be sorted between the two? Take, for example, the well-known *Sequoiites Couttsiae*. Its foliage, using the criteria of Buchholz, would bar it from *Sequoiites*, and its cone, apparently, would bar it from *Sequoiadendronites*. Must we straight away found a new fossil genus for it? That way lies chaos. This again is scarcely the place for a survey of the relations between living and fossil Sequoias, but looking, without any special bias, at the fossil record as a whole, surely it is simplest, with our present knowledge, to take it as it appears to be, namely, the record of a widespread genus with a good range of form in foliage and cone, and it is surely simplest, for the present, to consider the two living redwoods as two surviving species, showing naturally certain marked differences, but differences within the gamut of the fossil range.

It is claimed, therefore, from this cursory survey, that against the background of intense human interest associated with the redwoods, there is no real evidence for a generic segregation. Ignoring the fossil record, as it does, the proposal appears based on the over-emphasis of points, long known to systematists and not of fundamental significance. The points of difference brought forward are either variable and intergrading or points which are definitely not given generic significance elsewhere in the conifers, even though shown in a more extreme condition. If the segregation of the two Sequoias is admitted on this evidence, such criteria must be applied to the conifers in general, and then a wholesale splitting of other genera must straightaway be made. Such splitting would affect, for a beginning at least, *Araucaria*, *Dacrydium*, *Juniperus*, *Podocarpus*, *Pinus* and possibly *Abies*. The logical issue might be, at the last, the institution of a separate genus for each species even reasonably distinct from its fellows.

Let us, then, leave those sentinels of the Sierras, the General Grant, the General Sherman, the Four Guardsmen, and the others, to stand watch in the centuries to come under a banner with the old familiar inscription—*Sequoia gigantea*

GEOLOGY OF THE PUNJAB SALT RANGE

By SIR CYRIL FOX

Lately Director, Geological Survey of India

MY first contribution to the discussions on the age of the Saline series or Salt marls in the Salt Range, both in the Punjab and in the trans-Indus area in Kohat, was published in 1928¹. Since then, several important papers on the subject have been published, by Messrs D N Wadia, L M Davies, G de P Cotter, E R Gee, and others. These have been very ably summarized by Dr W D West in a paper entitled "Some Recent Advances in Indian Geology. The Geology of Salt Range"². In the meanwhile, Mr E R Gee has completed his seven years careful and systematic mapping of the Punjab Salt Range and its continuation across the Indus into the North-West Frontier Province. He in 1939, finally arrived at the conclusion that the Saline series or Salt marls occupy a stratigraphical position below the marine Lower Palaeozoic strata and should be regarded as pre-Cambrian in age. Now quite recently Prof Burbal Sahní and his co-workers in palaeobotany at Lucknow have announced the discovery of abundant microfossils in the Salt marls³.

In the above-mentioned contribution Prof Sahní writes "Fossils found in the Saline Series in recent years have repeatedly suggested that the beds are early Tertiary or even younger. But the value of the evidence has been questioned. In view of these objections, I collected some lumps of rock-salt with intercalated thin laminae of saline earth or 'kallar' from positions deep within the salt mines, with the view of examining the kallar for possible microfossils. The investigation of this material has given results beyond all expectation: the bands of kallar must be teeming with signs of life, for every single piece has yielded microfossils. The great majority are undeterminable as to genus and species, being mainly shreds of angiosperm wood, but there are also gymnosperm tracheids with large round bordered pits, and at least one good, winged, six-legged insect with compound eyes. These facts suffice to prove that the Salt Marl of the Punjab cannot possibly be Cambrian or pre-Cambrian as suggested among others by Dr Murray Stuart, Sir Cyril Fox, and now also by Mr E R Gee, until recently a strong advocate for the Eocene view."

No one has, nor will, question the importance of these discoveries now recorded by Prof. Sahní—the presence of abundant microfossils in the kallar or red saline clay, which is found associated with the rock salt in the cis-Indus mines, but appears to be absent or rare in the trans-Indus exposures. It is quite another matter where the interpretation of these facts is concerned, because the meaning of the term *in situ* needs explanation in relation to original sedimentary deposition, as will be discussed later. Dr Sahní's communication conveys the impression that the microfossil assemblage is younger than Lower Tertiary (Eocene), the age which is usually ascribed to the Salt marl by those who have supported the idea that the Saline series is of Tertiary age. In view of Mr Gee's mapping and the Lower Palaeozoic to pre-Cambrian age which he has been obliged to admit, the question for the present must be how these Tertiary microfossils have found their way into beds which lie below those with a marine Cambrian fauna and are considered pre-Cambrian in age. It is to be

remembered also that Mr Middlemiss was so struck with the unaltered condition, both dynamically and chemically, of these Lower Palaeozoic formations the Punjab Salt Range that he compared them with the pages of a volume fresh from the binders' hands.

Mr Middlemiss' original remarks are well worth reading⁴. Although so old, the original sandstone shales and limestones remain as such and have not been converted into quartzites, slates or marble. It is the case with equivalent strata in the Himalayas. Nor are these beds in the Punjab Salt Range fourfold or even severely buckled in any widespread kind of way such as is common in regions of orographic mountains, as those in the trans-Indus area of the North-West Frontier. Beneath these unaltered Palaeozoic strata lie the plastic and soluble deposits of rock-salt and saline marl (kallar) of the Saline series, and above the Palaeozoic strata there are younger formations successively upwards to Lower and Middle and Upper Tertiary (see section given in Dr W D West's summary²). In the exposures seen along the scarp of the Punjab Salt Range the salt marl are the most disturbed where, as might be expected, such plastic material is able to escape outwards from under the weight of overlying strata and the overlying formations are seen to be tilted; though by block-faulting and, in places, have sunk into the marls (see ref 1, plate 9). In other places there are evidences of subsidence by the actual solution of the salt, as occurred in Khewra village in 1925, when it was found that a spring of water was removing salt in solution at the same rate as organized mining was producing salt for the Government of India.

At Pidh, on the Dandot plateau of Nummulitic limestones, the drainage is enclosed and sinks underground, and the water presumably carries some silt and such material in suspension with it. No details of the movements of such waters, or of the material they carry, have been made known, but there is very little doubt that such an investigation will yield interesting and perhaps surprising results both as regards the salinity of the water and the material carried in suspension at different stages of its journey. Indeed, it is quite well known that pieces of wood and even the trunk of a tree (of a type now found growing on the hill slopes) have sunk down so-called 'swallow-holes', and are met with embedded in the solid rock-salt as though by movements akin to regelation. The kallar itself was thought, by Dr W A K Christie, Dr Murray Stuart and myself, to represent the insoluble residue which is left when rock salt has been dissolved and removed in solution⁵. Indeed, it is not uncommon to see 'pipes', which are filled-up sink-hole channels, down which water came but which were later choked up with transported solid residue or saline red clay very similar to kallar.

So long ago as 1878, when writing the official opinion of the geology of the Saline series, which were then regarded as probably Infra-Silurian (in the Murchisonian sense that the Silurian included the Cambrian), Dr W T Blanford wrote as follows⁶:

"Owing to the softness of the marl, and to the tendency of harder rocks to slip upon it whenever it is sufficiently saturated with water, to destroy its coherence, and also to the salt beds being dissolved by water, the rocks of the Salt Range are broken and mixed up in a most complicated manner, masses of the marl having been squeezed by pressure in places into a position in which they appear to overlie more recent rocks, while all the newer formations are

cracked and faulted. The detailed geology of the range is consequently very intricate, and it is not always easy to tell whether dislocations of the strata are due to true faults traversing all the beds, inclusive of the salt marl, or whether the displacement is merely due to complicated landships."

Dr Blanford did not comment on the exceeding solubility of rock-salt (20,000 times that of limestone) or on the extreme plasticity of the saline marl, but these factors are thoroughly well known to-day, and will be appreciated by those who know the solvent effects of water on limestone—the various grottoes and caves, the removal of a bed of limestone beneath coal-bearing strata at Cherrapunji (Assam), the formation of bauxite (*terra rossa*) in the *dolinas* of Istria, etc.

Those who have a good knowledge of the probable depositional conditions—climates and land distribution—in the various geological epochs since Lower Palaeozoic era in the Indian region are well aware that an arid period almost certainly prevailed when the Upper Vindhya and their equivalents in the Salt Range—the Purple Sandstone—were laid down in early Cambrian or pre-Cambrian times, which, according to Mr Gee, and those of us who have held the same opinion previously, was soon after the rock-salt deposits had formed in the Punjab area. These desert conditions and marine associations were widespread at that early epoch of the historical geology of India and adjoining countries to the west, so that there is nothing improbable about the geographical aspects of a pre-Cambrian to Cambrian age for the Punjab rock-salt occurrences. On the other hand, there is little such evidence in support of an Eocene age for these deposits, and my own special studies of the coalfields of Baluchistan, the North-West Frontier Province, Kashmir, the Punjab and Rajputana can find no epoch when marine and climatic conditions could favour the deposition of salt on a considerable and widespread scale. Better possibilities may have existed in middle and upper Tertiary times, but so far as I know there has been no one who has claimed a younger age than Eocene for the rock-salt deposits of the Punjab or of the trans-Indus area. It is difficult to conceive of such conditions over the Salt Range area of the Punjab in middle Tertiary times and more so for such an upper Tertiary epoch, geographically at least.

The problem, therefore, seems to be to discover how the microfossils, found by Dr Sahni and his co-workers in the Punjab Salt Range, have been carried into the Salt Marl or Saline series which are regarded as Cambrian to pre-Cambrian in age. Also, and this is a similar problem, how it is that Messrs P. Evans and M. A. Majeed were able to show that the heavy mineral residues, from samples of the Salt Marl, agreed most with the results obtained from Tertiary strata. I have not seen these results and do not know with what Tertiary strata the Saline series would be correlated on this kind of evidence. I have had the reliability of the heavy mineral assemblages tested by obtaining samples of sand from the Damodar—in its upper waters, at several places on its course through the coalfields and finally where it enters the Burdwan alluvial plains—and found that the proportions of certain heavy minerals were remarkably persistent. This may thus suggest the idea that the streams flowing underground to the Salt Marl may have carried heavy minerals down with them with the same persistency of proportions prevailing as those in the rocks from which the water derived its heavy minerals. There may thus be no

evidence to prove that the Saline series are of the same age as the residues, from residues found in the rock-salt deposits. I suggest that the same argument applies to the microfossils. Incidentally, full details are not yet available of these microfossils, and a great deal more has to be done, such as a search for similar remains in the Tertiary strata of the Salt Range.

A small field committee consisting of Dr H. Crookshank and Mr E. R. Gee of the Geological Survey of India, with Dr E. Lehner and also Messrs E. S. Pinfold and J. Coates, geologists of the chief oil companies in India, are, at the time of writing (November 7, 1944), in the Salt Range to re-examine all the critical geological sections. They will no doubt give the subject of Dr Sahni's microfossils and Mr Evans's heavy mineral assemblages the most careful consideration [see p. 266 of this issue of *Nature* Eds.] They are also unlikely to leave the question of the gypsum unattended to, but in this connexion I would say that the conversion of limestone into gypsum is not a remarkable phenomenon if the necessary conditions are favourable and a decomposable sulphide, such as pyrite, is available. The gypsum is, of course, a secondary product whatever might have been the age of the original materials involved—limestone and pyritiferous coal as an example. It is very likely, indeed to be expected, that a careful examination of the gypsum for microfossils and heavy minerals would provide evidence as to the age of the original substance, for example, limestone. It does not follow that this method of determination will fix the age of the strata in which the gypsum occurs, because the limestone (if so proved) might have been xenolithic. For example, it may be in other strata than those belonging to the beds in which the limestone was deposited and in which it was originally truly *in situ*.

In contrast with the absence of tectonic folding in the strata above the Salt Marl in the Punjab Salt Range, as around Khewra and Dandot, the beds associated with the rock-salt in the trans-Indus areas are characterized by folding. Highly inclined beds with evidences of synclinal and anticlinal structures are common. Indeed the rock-salt occurrences appear to be normally found in faulted anticlinals in this Kohat region. It is just the position in which a plastic substance might be expected if it had been squeezed up from below by the dynamic forces of folding. The salt certainly appears to have been extruded upwards by great tectonic pressure, and shows evidence of this in its own texture. From a distance of only a few yards the rock-salt can often be mistaken for gneiss, as it possesses a gneissose structure, but is thus entirely different from the rock-salt in the Punjab, which appears to have escaped this degree of dynamic force. This is in general agreement with other observations. The trans-Indus region is closely involved in the orographic mountain ranges of the Indian borderland, while the Punjab Salt Range can scarcely be claimed to possess any orographic axis and is largely the southern scarp of a plateau region. It is for this reason that the supporters of a Tertiary age for the Salt marls have usually invoked an almost flat plane of sliding for the superincumbent strata. It is needless to say that over-thrusting for twenty miles or so in a region evidently devoid of serious folding has always been a mechanical defect in such explanations.

It must therefore be recognized that the two regions—the *cis*- and the *trans*-Indus—are orographically different, although one passes almost insensibly into the other. For this reason the rock-salt

SCIENCE IN PEACE

has behaved differently under tectonic squeeze—which was very severe in the trans-Indus area and almost absent in the Punjab area. The salt deposits are probably of the same age—laid down in Cambrian and pre-Cambrian times. They were protected by overlying strata until comparatively recent times, when erosion in the Punjab area and dynamic folding in the Kohat region have disclosed these valuable deposits, which have been preserved for us since the Lower Palaeozoic age. The treatment of the plastic salt in the folded strata will fully explain how it escaped upwards along a fault into an anticlinal, also how it was carried upwards or became entangled with newer strata—nummulitic limestone, oil shale or pyritiferous coal, and further, how when conditions and material were favourably disposed, gypsum has formed—from the included or xenolithic fragments in the rock-salt or adjacent to it in the strata from which the xenoliths were derived. The *modus operandi* in the Punjab area was somewhat different, it consisted of subsidence by solution and transport by underground water, whereby blocks of stone, tree stems and other derived material (such as microfossils and heavy minerals) have become embedded in the salt and in its insoluble residue (the kallar) in the Saline series of the Punjab areas. In neither case, however, *cis-* or *trans-*Indus, are these incorporated materials strictly *in situ*, and thus any gypsum formed from such derived material is, so to speak, truly *tertiary*, but in a *primary* setting.

In conclusion, I would like to quote a few lines from the last report submitted to the Government of India by Mr. H. B. Medlicott, director of the Geological Survey of India, before he retired in 1886⁷. He wrote:

"The geologist's work is therefore sound and useful or false and misleading in proportion to his real acquaintance with the actuals and the principles of the exact sciences, and unless he reaches a certain standard of excellence his work is absolutely useless, or worse. In this respect the geologist is unique. A doctor may acquire a useful skill in the practice of medicine without being anything of a biologist; an engineer may do fair work with little or no knowledge of mechanics, a man may be a surveyor without any proper knowledge of geodesy or astronomy because in all these businesses there are practical rules by which ordinary work can be safely executed. Geology is the opposite of all this: there is no operation called for every act in its service is an independent judgment upon very complex inductive facts through an accurate knowledge of physical phenomena and their laws, if not scientific it is nonsense. Further it is to be noted that the data upon which the geologist has to frame his judgments are for the most part very scanty from occasional scattered sections or single outcrops he has to attempt the representation of the rocks as they lie underground and their remote history. Thus, though based on the exact, it is itself the most inexact of sciences, and eminently demands conscientious and sober judgment. There is no science with which it is so easy to acquire a superficial acquaintance and to play the impostor."

THE most striking characteristic of the open conference on "Science in Peace", organized by the Association of Scientific Workers at Caxton Hall, Westminster, on February 17 and 18, was neatly expressed by Prof. J. D. Bernal in his final summing-up of the Conference. The content of the fifteen papers submitted in three sessions devoted respectively to "Science and Production" (chairman, Prof. P. M. S. Blackett), "The Future Development of Science" (chairman, Sir Robert Watson-Watt) and "Science in Everyday Life" (chairman, Prof. H. Levy) had, he said, had the quite remarkable quality of having been 'orchestrated'. An account of the whole opus will accordingly be attempted here, not by separate discussion of the component movements, but by tracing the *leit-motiv* which recurred so clearly, inevitably and appropriately through all. They are all familiar themes enough, but their interrelations took new emphasis, and their combined intellectual and emotional appeal was profound. They were expansion, investigation, documentation, publication (the key theme in some expected and some less expected contexts), organization, integration, mechanization, standardization, nationalization.

The Conference opened appropriately with a paper on "The Future of British Economy", by G. D. N. Worswick, and closed equally appropriately with one on "The Place of Science in Culture", by Prof. B. Farrington. The whole argument of the Conference was necessarily based on an expansionist economy providing full employment, the practicability of continuous full employment is in large measure governed by the full utilization of science, including the scientific control of processes, on the other hand, potentially revolutionary applications of science in industry are only acceptable to the workers if their justifiable fears about continuity of employment are categorically answered by a declared Government policy for assured and continuous full employment. The honouring of such an assurance depends on giving to the public interest its rightful place relative to private interest, and this in turn can only be assured by a substantial measure of Government control. No point made was more heartily applauded than the statement that bureaucracy is far more prominent and harmful in the larger aggregations of 'private' enterprise than in Government departments. Government control, varied and adapted to the needs of public interest in application to each main industry, must be control by the people acting through a democratic government in the interests of the people. The overall success of government control in the greatly expanded industry of the war effort was cited as an augury for the future.

The paper by Mr. Joe Scott, member of the Executive Committee of the Amalgamated Engineering Union, on "Science and the Productivity of Labour", emphasized the role of science in improving the conditions of life of the worker while at work and at leisure, in lightening labour and improving the use of leisure in avoidance of injury and improvement of health. He stressed the inseparability of science from production, it was another of the recurrent themes of the Conference that we are no longer dealing with separable applications of science to industry, that we are now at a stage where scientific method should be inherent in every step of the industrial process, where the permeation of science through the whole of industry is a happily

irreversible process preventing the picking out of amplexes to be exhibited as 'science in industry'. This permeation of process demands a corresponding permeation of organization, in which the place of scientific work in the national economy is recognized and insured by detailed interlacing in an industrial democracy, at all levels and in all significant groupings. An important element in this permeation is a much closer co-working with the trade unions, individually and collectively.

Mr Scott introduced the two themes of investigation and documentation, with examples of welfare and health investigations, which could not have been carried through save by the machinery of the trade unions and shop stewards, and, from another angle, with a plea for direct availability to trade union negotiators of the scientific and technical facts which they require to support and answer statements made in negotiation.

This was one aspect of a universal demand for public availability of the facts—many already known privately, many not yet known even to managements in private enterprise—by which the efficiency and potential of any stage in the industrial process can be measured. The filling of the gaps in private and public information is essential to progress, and involves the large application of the methods of operational research within industries. There is need, indeed, not merely for organized research but also for research on organization, the appropriate structures for scientifically operated and publicly controlled industry are still in large measure unknown or ill-understood.

The demand for publication as a safeguard of the public interest was pressed at every session and thus in many different connexions. If it were necessary or desirable to condense in four words the essence of the discussion on "Science in Everyday Life", the words might well be "Publish and be Blessed". Full and free interchange of knowledge not only from scientific research, but also from studies on organization, not only on engineering efficiencies but also on economic efficiencies, 'all facts on the table' was regarded as essential to increased productivity, to improved conditions of life, and to the avoidance of diversions in favour of private interests.

"The Organisation and Finance of Science" were discussed by Dr S Lilley, who argued the case for the Association of Scientific Workers policy in favour of a national research and development council, responsible to the Lord President of the Council, for surveying national needs and resources and planning the broad lines of scientific work to meet the needs and develop the resources. The Council would plan the strategy of attack on these problems, it would neither execute the work in laboratories of its own nor interfere in the tactics of work in the laboratories, of existing types, to which it would allocate broad responsibilities and adequate finance. Expenditure at the rate of some twenty-four million pounds per annum, as compared with our pre-war seven million pounds per annum, it was stated, is required, a great expansion of laboratories would be needed, the research associations would be key factors in the plan, and no industry would be allowed to stifle co-operation by the withholding of financial contributions, the naive form of subsidy-without-supervision represented by tax remission on alleged research should not be permitted, publication of results would be insisted on. The new organization would require the participation of the representatives of the

people in general, and of the scientific worker in particular, at all levels in the formation and execution of policy.

An important part of the problem of the deployment of our scientific forces is the striking of a balance between long-term fundamental work and short-term work of direct and immediate application. The chairman of the session on "The Future Development of Science" described the problem as one in the "intellectual economics of the social conscience", Prof Blackett emphasized the high long-term productivity of fundamental science, which must pass from its old state of self-determination towards an imposed orientation arising from increased direct support from public funds. This fundamental science must be guided by men of science, acting under broad directives on social objectives coming not from a bureaucratic Civil Service but from public opinion through Parliament and the Government answering to Parliament. An important part of this direction must rest on the economic policy adopted by the nation, there is virtually no limit to what science can do, there are limits set by economics on what it is worth doing, for example, in developing synthetics and substitutes as an alternative to importing. A short-term crisis, such as the present War, is the only exception to the law which forbids the sacrifice of the big future dividends offered by fundamental research to the smaller quick returns of too closely applied development.

Both Sir Robert Watson-Watt and Prof Blackett directed attention to the need for a federation which could speak with the voice of the scientific practitioner at large, on a wider basis than the highly selective Royal Society and the highly specialized professional institutions, including the Association of Scientific Workers, with its vitally important trade union affiliation, but not excluding those who do not recognize that affiliation as necessary or desirable.

Prof Bernal, in his contribution on the future development of "Applied Science and Technology", carried the development of the theme of 'organization' into the enunciation of the theme of 'integration'. The application of science is the practical side of the war against poverty and calls for the same spirit and intensity of organization as the current War. The revolution in the relations of science to industry is now far advanced, the essential now is the complete integration of science with industry, the dual problem is to make industry scientific through and through, and to make this possible by demonstrating to the public the need for this permeation and integration. The public has still far to go in appreciation of the need: it is still merely 'gadget-minded'.

This integration demands the full democratization of science in industry, democratization is far less advanced in industry than in politics. One necessary element, that of public criticism, is provided in the political sphere by Parliament, it could be provided in the sphere of industrial science by trade union organization. Only the scientific worker can determine the mode of application of science in industry, for this he must sit in the board room of management for the formation of policy, he must equally find his place in the joint production committee.

Integration, as was shown in those contributions to the first session which dealt with the basic industries of Britain, must be carried over the whole area of each industry and across the frontiers between industries, the separation of the generation of gas

from the generation of electric power and of both from the full utilization of coal is as artificial, irrational and wasteful as is the treatment of the coal industry as something apart from the chemical industry, of which coal is the very foundation

Discussion on the coal industry was the most important single development of the mechanization theme, and it led to the conclusion, not from any devotion to nationalization as a good-in-itself, but from lessons in the long unhappy history of that industry in particular, that mechanization in coal-getting would not be attained without governmental control so firm and detailed as to mean nationalization. The applicability of any such simple prescription as 'American machinery everywhere' was recognized, but there was a clear conviction that a plan of mechanization measured to the geology and the degree of past working is of extreme importance.

The discussions, which brought in variations on the theme of mechanization, interwove it so intimately with the theme of standardization that an answer to criticisms of 'dullness through standardization' was specially important. It was pointed out that general availability of the products of industry depends on the wide extension of mechanization, that mechanization can only be reasonably effective if the production runs are long runs giving large numbers of one pattern, and that consequently the total number of patterns available to the total field of consumption would be reduced. This does not, however, mean that the average consumer, with limited purchasing power, has a reduced range of available patterns. He would, in fact, have access to a wider range of better models, brought within his reach by the economies in cost attained through mechanization.

The Conference was made notable by the resumption of personal international contacts on a scale only now becoming possible as the war situation improves. The Sunday morning session was marked by the enthusiastic reception of addresses by Dr Marcel Matthieu, a member of the executive committee of the French Association of Scientific Workers, and

by Prof. A. Danilov, chairman of the U.S.S.R. trade union covering scientific and ancillary workers in the laboratories of the universities, the academies of science and the research institutes. Prof. Danilov was accompanied by four other Soviet colleagues. It was noteworthy that the Soviet delegation to the World Trade Union Congress meeting in London included three scientific workers.

The Conference adopted at its closing session a resolution in the following terms:

"This public conference which has met to consider the tasks of science after the war, records its whole-hearted admiration of the fighting forces of the United Nations whose great achievements are bringing peace nearer at hand. Their deeds are providing the foundations for a better world while the advance of science and technique are the tools with which it can be built. This conference declares its conviction that

(1) The achievement of a progressive rise in the standard of living of mankind needs the fullest use of science and technique within the framework of a world expansionist economy

(2) An expansionist economy policy at home implies assistance to the backward and undeveloped countries to raise their productive level by the establishment of modern industry and scientific agriculture

(3) In this country the advanced and efficient application of science requires democratic planning largely by scientists themselves. For this we propose a central research and development council under the authority of the Lord President of the Council

(4) The problems facing the manual workers in the future, arising from the effect on their working conditions, of scientific and technical advances, demand close collaboration between the organized scientists and the rest of the Trade Union movement

(5) The closest collaboration must be achieved between the people of all nations, including the fullest interchange of scientific and technical knowledge based on the contacts now being built between the scientists in Great Britain and the Dominions, the U.S.S.R., France and the U.S.A."

NEWS and VIEWS

Chemical Engineering at Cambridge

THE period extending between the two World Wars has been remarkable for the advances made in what is usually termed 'technology', and it is especially in chemical technology that this development has been most rapid and spectacular. A scientific discovery in a chemical research laboratory may be the progenitor of a finished manufactured article, but the aims and objects of the discoverer and those of the manufacturer are quite different. Since the manufacturer is interested in producing an effect, and since also economics plays an important part in his considerations, it is clear that many steps alien to a pure research laboratory have to be taken after a discovery has been made before a plant is in actual operation. We are confronted with the problem as to the most suitable training for such workers in chemical technology. Prof. Haber, who was at Cambridge at the end of the War of 1914-18, when asked what English chemical industry needed, replied that our weakness lay in not applying the methods of physical chemistry to industry. There is more than a germ of truth in

this. Chemical engineering may be regarded by some as a misnomer for chemical technology, and it is within the orbit of physics and chemistry rather than engineering that the new development should take place.

The larger industries in Britain can train their own men, but this is impossible in smaller units. The training given in the Technische Hochschulen on the Continent, or the Massachusetts Institute of Technology in the United States, has proved eminently successful in the respective countries. In Great Britain it appears that such further development as is required will take place in the universities. Hence the munificent gift of about half a million pounds by the Shell Group of oil companies to the University of Cambridge for the endowment of chemical engineering comes at an appropriate time. The University, in accepting this, has likewise incurred a great responsibility. It is generally recognized that we have much leeway to make up to survive in the post-war world as an industrial nation. The chemical industries of Britain are by no means

the least important contributors to the country's wealth and may well become a dominant factor. Increased burdens will be placed on the nation's chemists and chemical engineers, and their training must be such that they can achieve the tasks that lie ahead. Care must be taken that the new Department is continually nourished by its roots—the subjects of chemistry, physics, mathematics and engineering, and those who pass through it should then build on sure foundations.

U.S. Research Board for National Security

ESTABLISHMENT of the Research Board for National Security by the U.S. National Academy of Sciences was announced on February 11 by Mr. Henry L. Stimson, U.S. Secretary of War, Mr. James Forrestal, U.S. Secretary of the Navy, and Dr. Frank B. Rowlett, president of the National Academy of Sciences. The Executive Committee of the new Board will be headed, by Dr. Karl T. Compton, president of the Massachusetts Institute of Technology, and the Board will consist of seventeen civilian men of science and nine representatives each from the army and navy, including Major-General Norman T. Kirk, Army Surgeon-General, and Vice-Admiral Ross T. McIntire, chief of the U.S. Navy Bureau of Medicine and Surgery. Civilian members include Mr. Herbert S. Gasser, director of the Rockefeller Institute for Medical Research, Prof. E. O. Lawrence, professor of physics at the University of California in Berkeley, and Prof. Isador I. Rabi, professor of physics at Columbia University. The Secretaries of War and Navy requested the president of the National Academy of Sciences under its congressional charter to establish the Board "to assist in providing for continued civilian participation in the longer-term scientific problems of national security when the Office of Scientific Research and Development proceeds to liquidate its activities as a temporary war-time agency. . . . The objective of the Board will be to continue, pending final consideration by Congress on creation of an independent agency, the close co-operation between civilian scientists and the armed services which has proven to be such a vital element in the prosecution of the war. Composed of high-ranking officers responsible for the needs and plans of the Army and Navy with an equal number of distinguished representatives of science, engineering, medicine and industry, this Board includes many of the features of the Office of Scientific Research and Development which has proven so successful as a war-time agency in mobilising civilian scientists and co-ordinating their work with the requirements and operations of the armed services. . . ." The announcement pointed out that "science is here broadly interpreted to include the employment of scientific method of analysis, experiments and tests in any branch of science or technology including engineering, medicine, psychology and biology."

Science and Planning

IN a memorandum "Science and the Real Freedoms" issued by the Association of Scientific Workers (price 3d), Sir Robert Watson-Watt gives a very fair appraisal, under the title "Freedoms of Science", of the issue between planning and freedom, successfully avoiding the political prejudices with which the discussion is apt to become entangled. Sir Robert's article is based on a speech delivered in Manchester last October. He insists first on the necessity for clearly defining our terms. Science he regards as

organized knowledge, but he considers that those constructive pursuits requiring for their prosecution, expansion and usefulness the application of a like process of thought are also properly covered by the term 'scientific'. The pure and applied sciences are in fact planned sciences. There is no human activity which is not a planned activity, and Sir Robert urged that we should consider whether organization in hope is not a nobler and more fruitful aspect of human endeavour than the organization of and through fear which has inspired our planning for war and even extended to the medical sciences. Asserting that the freedom to learn, to choose, to think, to work and to speak are the fundamental freedoms of the individual and the pillars of any tolerable society, Sir Robert urged that the real question is whether planning—which is inevitable—is to be open and public, or sectional, secret or selfish. He visualizes a structure in which the user who wants a definite result asks the research worker, the developer and the producer how best, by what particular kind of planning, he can attain his result, the research worker, the developer and the producer co-operate with the user, indicating to him the full possibilities. The greatest danger is over-simplification, but the planning of science in the application to national life is possible with no substantial risk to the freedom of fundamental science.

Education and Training for Engineers

IN a second report now issued by the Institution of Electrical Engineers, it is suggested that provision should be made for the education of craftsmen, technicians and professional engineers. There should be a three-year course for a craftsman certificate, followed by a more general course, lasting two years, in workshop administration. For the technicians group, the existing course for the ordinary national certificate in electrical and mechanical engineering should be co-ordinated as a basic course, and this should be followed, where necessary, by a course in advanced technology. Students who do well in the first two years of the ordinary certificate course should be combined with those who have reached the standard of a good school certificate in mathematics and physics, and these students should enter a two-year course leading to an intermediate national certificate designed to meet the requirements of the Section A examinations of the Institutions of Civil, Mechanical and Electrical Engineers. These courses would lead to the higher national certificates in electrical engineering and kindred subjects. Another section of the report contains proposals for the further education and training of electrical engineers returning from the Services.

University of Birmingham

THE Court of Governors of the University of Birmingham has nominated Mr. Anthony Eden for appointment as Chancellor of the University in succession to Lord Robert Cecil. The Pro-Chancellor (Mr. E. P. Beale) has announced that a public appeal for £1,000,000 will shortly be made to enable the University to proceed with urgently needed developments, especially the bringing together on one site of all the departments (some of which still remain in the centre of the city) and the building of additional halls of residence. Many of the donors to the appeal for £250,000 for rebuilding and re-equipping the Departments of Mechanical and Electrical Engineering have expressed the opinion that a great need of

the provincial universities is a fuller communal life for the students, such as can be secured by halls of residence

Electric Discharge Lamps for Photography

MR H. K. BOURNE presented a paper on this subject, illustrated by a comprehensive display of typical lamps, at a meeting of the Association for Scientific Photography on January 27. Photographically, electric discharge lamps have high actinic efficiency combined with low heating power, and they have a long life. Since the early days of the Cooper-Hewitt lamp, a glass tube several feet in length with a mercury pool at the end, development has proceeded along two divergent lines, low pressure and high pressure. In the modern low-pressure lamp, the pressure of mercury vapour is only a fraction of a millimetre, it emits considerable long- and short-wave ultra-violet radiation, which by means of fluorescent powders on the inside of the tube is converted to visible light of longer wave-lengths. It provides a well-diffused light-source closely resembling daylight and capable of giving accurate colour rendering. The high-pressure mercury vapour lamp consists of an inner glass tube containing the arc, sealed into an outer glass jacket. The arc tube pressure is about 1 atmosphere, and the arc is constricted into a narrow cord along the axis of the tube. The outer envelope is filled with an inert atmosphere. There is a wide range of types, the most powerful being in powers of the order of 10 kW or higher, with a brightness ranging up to 100,000 candles per sq. cm. The spectrum is linear in character, and fluorescent powders cannot be used with the high brightness lamps, but with increasing pressure there is an improvement in the colour, the main lines broadening while the amount of continuous background increases. An amalgam of cadmium is sometimes used to improve colour. Brightness increases with increases of loading per unit length in the arc column, which has been made possible, first by the use of quartz tubes with molybdenum foil vacuum-tight seals, and later by the introduction of water-cooling, which dissipates approximately 70 per cent of the radiated heat. The author described a number of lamps including a compact source lamp with a maximum brightness of 18,000 c/sq. cm., a self-contained metal box-lamp which can be used without a lamphouse for the illumination of laboratory instruments, a 100-hour-life water-cooled high-pressure lamp with a luminous efficiency of 65 lumens per watt, a peak brightness of 30,000 c/sq. cm. and an internal pressure of about 75 atmospheres, and the B.T.H. syroscopic tube which can give recurring flashes at a predetermined frequency or be employed as a synchronized flash-lamp for ordinary photography.

Resources of Ireland

IN celebration of the centenary of the publication of Sir Robert Kane's "Industrial Resources of Ireland", the Royal Dublin Society has published (price 2s. 6d.) a number of lectures delivered before the Society last August, under the general title of "The Natural Resources of Ireland". Prof. M. A. Hogan, in reviewing the fuel resources of the country, does not see much hope of increased coal production, but believes that resources of the limited coalfields are sufficient to last at least 250 years. He foresees, on the other hand, a great increase in the use of turf, provided that mechanized means of cutting it can be devised. This would entail the preliminary easy drainage of

large areas of bog, in order to bear the weight of heavy cutting machines. Mr. J. A. O'Riordan discusses the possibilities of water power. The Shannon and Liffey schemes have made a notable beginning, and their theoretical capacity is estimated at 84,000 horse-power. Gauging stations on other rivers and possibilities, still unmeasured, of smaller streams promise great accretion to these resources. Mr. O'Riordan thinks that the potential production of hydro-electric power could eventually be doubled. It is to her water-power resources that Ireland must clearly look for energy in the future. A review of the mineral resources other than fuel, by Mr. D. W. Bishop, shows little of importance except phosphates. The metallic mineral resources are very small. Some ores, in small supply, seem to have been exhausted.

Studies on Pollen Analysis

THE study of pollen has come much to the fore during recent years. The pollen analysis of peat has become one of the most important techniques used in the study of post-glacial vegetation. Partly in view of the necessity of studying such geological data in terms of processes now in operation and partly in order to obtain information relating to plant allergens research is now being directed toward fundamental problems relating to the liberation, dispersal and deposition of air-borne pollen. The results will have obvious implications in the field of floral biology and should also be of value to the meteorologist. The pollen of insect flowers is receiving attention as a means of determining the source of samples of honey. All the above studies have, up to the present, been referred to under the general heading of pollen analysis. The need for a better name has been expressed in *Pollen Analysis Circular*, a cyclostyled research bulletin edited by Prof. Paul B. Sears, of Oberlin College, Ohio. Messrs. H. A. Hyde and D. A. Williams, of the National Museum of Wales and Llandough Hospital, Cardiff, respectively, in the October issue of that *Circular* suggest the term *palynology* (Gk. *παλύνω* (*paluno*), to strew or sprinkle, cf. *πάλη* (*palē*), fine meal, cognate with Latin *pollen*, flour, dust) for the study of pollen and other spores and their dispersal, and applications thereof. It is hoped that the sequence of consonants p-l-n (suggesting pollen, but with a difference) and the general euphony of the new word will commend it.

Motor Control-Gear

A PAPER read recently in London by D. Rudd before the Institution of Electrical Engineers reviews, in general terms, present-day practice in the design of industrial motor control-gear. The scope of the paper is limited to standard industrial equipment and the subject is approached from the user point of view. The first part reviews the principles on which modern design has been established, and the later sections discuss some of the factors that are likely to affect future development. The author states the case for the utmost simplicity in design and for greater latitude in the value of allowable starting-current peaks. Possible development in contact materials is discussed, and reference is made to the possibility of achieving some measure of standardization.

Veterinary Medical Institute

ACCORDING to the December issue of the *Anglo-Swedish Review* a new veterinary-medical institute has recently been inaugurated in the northern out-

karts of Stockholm One of the largest and most important departments is that for the production of horse serum The stables with boxes for about eighty horses have been built with slanting lantern-roofs which let in the light above the boxes, and every box is provided with running water Each of the horses produces about seven litres of blood, or raw serum, a week Hot and cold air is supplied according to the season In another and equally well-kept section are quarters for a large number of calves The Institute comprises three sections: a pathological, a bacteriological and a serological section, which are supplemented by a mechanical and a parasitic laboratory Altogether about 150 persons are employed The new Institute provides increased facilities for effective combating of diseases of domestic animals, which still cause heavy losses.

American Birth-rate

ACCORDING to statistics of the Metropolitan Life Insurance Company (*J Roy Inst Pub Health and Hyg*, Jan 1945), young mothers between the ages of twenty and thirty having their first child have been the principal contributors to the rapid war-time rise in the American birth-rate The chief factor in the rise at these younger ages has been the increase in the marriage-rate, but a good part of the rise has been accounted for by women who had delayed having children until economic conditions were more favourable Although the general birth-rate increased rapidly during the war period, the trend towards small American families as well is still in evidence, and families with five or more children continue to decrease

Bright Light Sources

A PAPER read by J N Aldington on November 14 last before the Illuminating Engineering Society gave a general survey of tungsten filament projector lamps, showing the trend of recent developments in this field The paper embraces consideration of the characteristics of tungsten filaments *in vacuo* and in gas-lamps employing both single-wound and double-wound helices, multi-filament lamps, and symmetrical light sources Various types of lamps are illustrated photographically, and lamp performance data are given in tabular form

Dried Starfish as Chicken Meal

IT is reported (*J Amer Vet Med Assoc*, 55, 151, 1944) that starfish, collected in the process of cleaning oyster beds, are now being dried and ground up to make chicken meal An analysis of the meal showed that it contained 30.7 per cent protein, 17.6 per cent calcium and 0.35 per cent phosphorus Tested against sardine fish meal of equal protein value, it proved its value as food, but its use had to be limited to 3.5-5 per cent of the total ration, because of the high proportion of calcium

University of London

THE title of 'professor emeritus' in the University of London has been conferred on the following: Prof. R H A Plimmer, who held the chair of chemistry at St Thomas's Hospital Medical School during 1922-42, Sir Owen Richardson, who held the Wheatstone chair of physics at King's College during 1914-24 and the Yarrow Research professorship of the Royal Society attached to King's College during 1924-44, Dame Helen Gwynne-Vaughan, who held the chair of botany at Birkbeck College from 1921

until her retirement in 1944 and was a member of the Senate as a representative of the Faculty of Science during 1929-34, Prof. Eva G R Taylor, who held the chair of geography at Birkbeck College from 1930 until her retirement in 1944

Dr C W Shoppee has been appointed to the University readership in chemistry tenable at the Royal Cancer Hospital (Free) Since 1939 he has been working at the Pharmaceutical Institute in the University of Basle

The title of professor of mathematics in the University has been conferred on Dr Paul Dienes, in respect of the post held by him at Birkbeck College.

Announcements

THE Medical Research Council has appointed Prof. A A Miles, professor of bacteriology at University College Hospital Medical School, London, to the staff at the National Institute for Medical Research as from October 1, 1945, with the view of his becoming director of the Department of Biological Standards on the retirement of Sir Percival Hartley next year

PROF. F Y HENDERSON, reader in timber technology in the University of London and assistant professor in timber technology in the Imperial College of Science and Technology, has been appointed director of Forest Products Research in the Department of Scientific and Industrial Research on the forthcoming retirement of Mr W A. Robertson, who has been director since 1933

MR V M WADSWORTH has been appointed assistant lecturer in agricultural economics in the University of Leeds

M TURGUT EREM, the first educational attaché to be appointed to the Turkish Embassy in Great Britain, has arrived in London, he will act as inspector of Turkish students in Britain, of whom there are now about a hundred, including eighteen holders of scholarships awarded by the British Council, with which M. Erem will be in close touch

THE Institution of Civil Engineers, with the Institution of Municipal and County Engineers, have appointed a joint committee to draw up notes for the use of engineers on the best location of underground services The Committee will consist of Mr W H Morgan, county engineer of Middlesex, as chairman, and ten other members, representatives of electricity and gas supplies and post office services have been nominated by or in consultation with the Institution of Electrical Engineers, the Institution of Gas Engineers and the chief engineer, G.P.O. respectively Communications should be addressed to the Secretary, Joint Committee, c/o Secretary, Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1

THE following appointments have been made in the Colonial Service: C F Charter, to be soil chemist, Gold Coast; R W Crowther and D A W Walker, to be veterinary officers, Nigeria; Miss M E Broughton, to be marketing officer, Nigeria; F E Luscombe, to be agricultural officer, Tanganyika; C Harvey, senior agricultural officer, Fiji; to be director of agriculture, Fiji; E W Leach, senior agricultural officer, Nigeria, to be deputy director of agriculture, Trinidad; F S Collier, conservator of forests, Nigeria, to be deputy chief conservator of forests, Nigeria

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

'Sensitizing' by Protective Colloids

THIS is the name given¹ to the following phenomenon. It was observed² that the addition of a quite small amount of a hydrophile colloid to a sol of a hydrophobe colloid caused the latter to be coagulated (precipitated) by a much smaller amount (at much lower concentration) of a precipitating electrolyte than in total absence of the protective colloid. However, suitable larger amounts of the latter made necessary larger amounts of precipitating electrolyte than in the absence of the hydrophile colloid, hence the term 'protective colloid' for the latter.

In a letter in *Nature* in 1921³ I suggested that many of the properties of the so-called (at that time) 'emulsoid colloids', and particularly of proteins, derived from a duplex character of their molecules in respect of their possessing both hydrophile polar and hydrophobe but organophile non-polar atom-groups. The conception was developed more explicitly in a monograph on gelatin⁴ to provide a basic *stratochemical* architecture for the micelles of proteins⁵.

Experimental evidence was presented from the effect of gelatin on the interfacial tension between water and toluene and from the sorption of gelatin at this interface out of dilute solutions⁶.

Recent investigations by me and my collaborators⁷ have shown that the adsorption of many basic dyes to silver halides occurs in two stages. In the primary—and priming—stage, the dye molecules are deposited in a mono-layer, with the polar or ventral (to suggest an anatomical image) aspect of the molecule (ion) adhering to the silver halide surface, and the hydrophobe (or dorsal) edge projecting into the aqueous solution. After saturation is effected, a second mono-layer begins to build on. This does not form a rigid but a reversible layer, of the Langmuir type, because now the non-polar hydrophobe aspects of the dye molecules are attracted each to each between solution and primary adsorbate, while the polar, hydrophile groups of the secondary layer are attached to the water.

There are complications attendant on the formation of dimerized and polymerized aggregates of the dye molecules which need not detain us here. What is important is that we now have evidence from direct adsorption measurements from dilute solution, as well as from experiments on the coagulation and reprecipitation of silver halide sols by dilute gelatin solutions, that a quite similar process to that with dyes occurs in the adsorption of proteins to the silver halides and other little-soluble polar solids.

The electrophoretic and kindred investigations of H. A. Abramson⁸ and many others have led to the general conclusion that "The fact that not only the isoelectric points but also the electric mobilities of quartz particles covered with serum albumin or egg albumin [or gelatin] are very nearly identical with the values of mobility for the respective dissolved protein indicates that practically all the polar groups of the protein molecules are available even after adsorption has occurred." The apparent paradox whereby the polar force fields of the protein should be quite free even when the molecules are at one and

the same time most tenaciously and strongly adsorbed⁹ to a polar surface is now explainable by our new observations, and the stratochemical layering. The electrical behaviour of the protein-coated silic particles etc., is due not to the primary mono-layer but to the secondary reversible layer.

It should be noted that the arrangement requires (of polar-nonpolar alternance, or 'amphipathy', to use Hartley's term) seems consistent with Astbury's X-ray diffraction conclusion that "polar and non-polar side chains follow one another alternately along the main chains" in the protein structure¹⁰.

The mechanism of 'sensitizing' evidently derives from the amphipathic character of the protective colloid, which is manifest not only in the proteins but also in such polyoses as the starches, dextrans, gums and pectins, and in kindred bodies, such as polyvinyl alcohol¹¹. Some part of the initial precipitating effect of these hydrophile colloids can be replaced by an alternate electrolyte—and vice versa. In all cases, the primary monolayer furnishes lipoid surfaces, coherence of which is coagulation. This is followed by reprecipitation by addition of further hydrophile colloid.

With my colleagues I shall deal with the subject more fully in subsequent publications.

Age of the Saline Series in the Punjab Salt Range

PROF. B. SAHNI's important observations¹ have necessitated a reconsideration of this problem. In order to review the geological evidence on the ground, an excursion was arranged to examine several sections which had led E. R. Gee, of the Geological Survey of India, and other geologists to the conclusion that the Saline Series of the Salt Range is of Cambrian or pre-Cambrian age. Prof. Sahni was unfortunately unable to take part in the excursion, the party consisting of the undersigned.

The sections visited were near Khewra in the eastern part of the range, and in the Warcha-Sakesar area of the middle western portion. This examination showed that an Eocene or later age for the Saline Series is irreconcilable with the field evidence, which, in our opinion, indicates that this series is Cambrian or older.

The junction of the Saline Series and the overlying Purple Sandstones (Cambrian or older) is in several sections conformable and transitional. This is well seen in exposures east of the Warcha Circuit House.

The junction of the Upper Carboniferous Talchir Boulder Bed with various stages of the Cambrian and the Saline Series was examined over several miles of its outcrop south of Sakesar. Here also our opinion is that this junction is normally an ordinary sedimentary overlap, thus precluding an age for the Saline Series later than Talchir.

Regarding the evidence of Tertiary to sub-recent fossils found by Prof Sahni, we observed so many instances, even deep in the salt mines, of sub-recent material being enveloped in the salt and in the marls, that it seems possible Prof Sahni's fossils had a similar origin, notwithstanding that in many cases they have every appearance of being *in situ*. Our conclusions were arrived at despite the recognition of certain difficulties, such as the occurrence of minute plant fragments of post-Cambrian age in the dolomites and oil shales, for which at present we have no clear explanation to offer.

The Foraminifera, formerly believed to indicate an Eocene age for the Saline Series², were later proved to be derived material embodied in outcrops as a result of subsequent movements.

Synergistic Effect of Cod Liver Vitamin D on Synthetic Vitamin D₃

ALTHOUGH the average vitamin D content of cod liver oil of authentic origin as produced by the world's fisheries in normal peace-time lies in the neighbourhood of 85 international units per gram, there are very wide limits of variation according to the season, condition of the fish in relation to spawning and the actual fishing ground on which the fish are caught. In our experience these natural variations cover a range from below 50 to above 500 international units per gram.

Experience with authentic cod liver oils shows that when oils of widely differing vitamin D potency are blended, the vitamin D content of the blend is in harmony with the calculated figure derived from the individual potencies of the components of the blend. This would be agreed as a matter of common experience.

On the other hand, we find that when synthetic vitamin D₃ is blended with cod liver oil, the assay in international units is higher than the calculated figure. Two typical results of tests using eighteen pairs of rats in each biological assay are given below.

Vitamin D content of the cod liver oil	Amount of synthetic vitamin D ₃ added to 1 gm of cod liver oil	Calculated vitamin D potency of the resulting mixture	Actual vitamin D potency of the resulting mixture
(I U/gm)	(I U)	(I U/gm)	(I U/gm)
90	80	170	206
84	81	165	245
89*	67	156	227

* Average figures for a comprehensive series of thirteen similar blends, using eighteen pairs of rats for each assay.

It is not the purpose of this letter to offer any final explanation of the apparent synergism between the vitamin D of cod liver oil and synthetic vitamin D₃. It is known, however, that the vitamin D of cod liver oil, often presumed to be a single substance is really a complex. Bills¹ and other workers have shown that there are at least seven forms of vitamin D. Hickman and Gray² have demonstrated by short-path distillation the possibility of there being at least six different substances in cod liver oil with antirachitic properties. On the other hand, the known synthetic forms of vitamin D are apparently individual substances which can, in fact, be crystallized in the pure state.

If the full activity of vitamin D as a therapeutic substance used to cure experimental rickets in rats depends on the simultaneous presence of more than one component, then vitamin D₃ itself, by reason of its singleness of nature, would not exert its full curative action until one or more of the other essential components of the vitamin D complex are adequately represented in the blend.

These observations have very wide implications especially in view of the different efficiencies for rat and chickens respectively of vitamin D₂ and various fish liver oils. In any event, vitamin D₃ can apparently become much more effective for rats if the vitamin D complex of cod liver oil is fed simultaneously to the experimental animals. It is a matter for further investigation as to whether the synergism of the type described between the vitamin D of cod liver oil and vitamin D₃ is general, or whether it is confined to the specific case of experimental rickets in rats.

Diabetogenic Action of Alloxan Derivative

THE finding of Shaw-Dunn and co-workers¹ that alloxan (and a styryl-quinoline) causes diabetes by damaging the pancreatic islet cells has since been amply confirmed in a number of laboratories, working with various animal species. Attempts to discover other substances with similar action have so far been unsuccessful, nor has any explanation been offered regarding the mechanism by which alloxan attacks the β -islet cells.

During an investigation of this question, a number of substances, all closely related to alloxan, were found to produce diabetes in rats when injected intravenously. These substances were methylalloxan, alloxantin, dimethylalloxantin, diuric acid, methylallic acid. Dimethylalloxan and dimethylallic acid (as sodium salt) were found to be highly toxic, the initial symptoms suggesting vagus stimulation, and did not cause diabetes in doses up to 100 mgm. per kgm. body-weight of rat. Renal damage, as judged by albuminuria and uraemia which was more or less evident with all these compounds including alloxan, was particularly pronounced with dimethylalloxan. Other disubstituted alloxans are now under investigation.

Diabetogenic action was not caused by tartronic acid, dimethylalloxanic acid (in which the fissure

the pyrimidine ring caused disappearance of the toxicity), alloxanic acid, violuric acid and murexide, the last three compounds having already been proved non-diabetogenic by several authors^{2,3,4}

It is of interest that the minimum effective diabetogenic dose is about the same with all these compounds, including alloxan namely, 50-70 mgm per kgm body-weight. This dose resulted in the development of extreme hyperglycaemia, glucosuria, polyuria and occasional ketonuria within 12-24 hours. These findings may indicate a very rapid conversion of alloxan to dialuric acid or vice versa, and an equally rapid decomposition of alloxantin. Alternatively, all these compounds might have some property in common, which enables them to interfere with processes within the pancreatic islet cells.

One of the best-known properties of alloxan and some of its derivatives is the decarboxylation and desamination of amino-acids, discovered by Strecker⁵ in 1862. We have examined some other substances which give the Strecker reaction. Ninhydrin, which is very toxic, did not produce diabetes in rats, nor did isatin, which is very sparingly soluble.

All the above diabetogenic substances were found to react *in vitro* with haemoglobin. The alloxans were methaemoglobin formers, while the alloxantins and dialuric acids rapidly converted oxyhaemoglobin into reduced haemoglobin and blackish-green decomposition products, probably bilirubinoid in nature. The latter effect was also observed *in vivo* with some of the dialuric acids. The alloxans, on the other hand, when given in normal dosage, failed to induce noticeable methaemoglobin formation in rats.

In conclusion, it may be mentioned that Jacobs² and Goldner and Gomori³ have reported negative results in attempts to produce diabetes with alloxantin and dialuric acid, using rabbits and dogs respectively. With a dosage of 150 mgm (super-saturated solution) dialuric acid per kgm we have, however, obtained diabetes in a rabbit after intravenous injection.

Liberation of H^+ , Al^{+++} and Fe^{+++} Ions from Hydrogen Clays by Neutral Salts

THE interaction between hydrogen clays and neutral salts gives rise to H^+ and Al^{+++} and, in a secondary measure, Fe^{+++} ions in the salt extracts. The mechanism of this reaction has been the subject of much discussion¹⁻⁸. Some investigators¹⁻⁵ consider that the acid liberated by the salt dissolves Al^{+++} and Fe^{+++} ions from the sesquioxides present in the hydrogen clay, while others⁶⁻⁸ postulate a direct exchange of Al^{+++} and Fe^{+++} ions for the cations of the added salt.

A number of publications⁹⁻¹² from this Laboratory have dealt with the liberation of Al^{+++} ions from hydrogen clays isolated from Indian soils by various neutral salts. At a constant pH the amounts of dis-

placed Al^{+++} ions (A) have been found to increase with the concentration (C) of the added salt. The plot of A against C has the shape of the usual adsorption isotherm. At a given equilibrium pH, barium chloride liberates a much larger quantity of Al^{+++} than hydrochloric acid. All these observations indicate a direct exchange of Al^{+++} ions for the cation of the salt, instead of their liberation by a secondary dissolution process. A direct exchange of both H^+ and Al^{+++} has been observed. At low values of C, very few Al^{+++} ions and mainly H^+ ions are exchanged. With an increase in C, the amounts of both displaced H^+ and Al^{+++} ions increase, but that of the latter at a relatively greater rate than the former. A relation has been found between A and the base-exchange capacity (B), calculated at the inflexion points in the titration curves with sodium hydroxide, of subfractions of hydrogen clay isolated from the same entire clay fraction. Both A and B usually increase with diminishing particle size. Any deviation from this regular variation in A with the particle size is also reflected in similar deviations in the case of B¹³. Depending on the nature of the hydrogen clay, an increase as well as a decrease in A accompanied by similar variations in B have been observed on the removal of free inorganic oxides present in the hydrogen clays according to the method of Truog *et al*¹⁴. The decrease in A and B probably indicates a decomposition of the absorption complex.

The amounts of H^+ , Al^{+++} and Fe^{+++} displaced from hydrogen clays Satara-F and Jorhat-F prepared respectively from a black cotton and an acid soil decreased to almost negligible values on continued leaching with a normal solution of barium chloride. But the above cations were liberated, as often the barium clay thus obtained was rendered desaturated by treatment with 0.02 N hydrochloric acid and then leached with a solution of N-barium chloride. Much smaller quantities of the cations were displaced from the desaturated clays compared with the original hydrogen clays. In the case of the hydrogen clay Satara-F, which contains the clay mineral montmorillonite, judged from X-ray studies¹⁵, and certain viscous¹⁶ and electrochemical criteria^{17,18}, the total amount of acid in its 'leachates' decreased progressively with successive desaturations. With the hydrogen clay Jorhat-F, containing mainly kaolinite and a very small quantity of montmorillonite, it tended to a constant value. The amount of Al^{+++} ions displaced from Satara-F decreased up to the fifth desaturation and then increased. In the case of Jorhat-F it decreased up to the fifth desaturation and then became constant. Very little (0.5 to 0.4 milli-equivalents per 100 gm of oven-dry hydrogen clay) Fe^{+++} ion was displaced by N-barium chloride from the two hydrogen clays. But with Satara-F its amount increased with successive desaturations up to the fifth one and then began to decrease. In the case of Jorhat-F it remained practically constant. The sum of the amounts of displaced Al^{+++} and Fe^{+++} ions decreased with progressive desaturations, tending to a constant value with both the hydrogen clays. After the full cycle of operations (eight desaturations in the case of Satara-F and six with Jorhat-F) a marked reduction¹⁹ in base exchange capacity (B) of Satara-F was observed. Jorhat-F showed no material change¹⁹. The observed reduction in B indicates a decomposition of Satara-F. X-ray diagrams obtained by Mr S. N. Bagchi¹⁵ gave no lines characteristic of montmorillon-

ite in the hydrogen clays at the end of the above cycle of operations. A relation between the mineralogical composition of the clay and the quantities of displaced Al^{+++} and Fe^{+++} ions is indicated by the above results. Further work with pure clay minerals is in progress.

These investigations have been carried out with the aid of a grant from the Imperial Council of Agricultural Research, India

Structure of Aluminium Trimethyl

THE existence of the dimer aluminium trimethyl has aroused considerable interest. Electron diffraction determinations^{1,2} are in satisfactory agreement with an ethane structure (I). However, this structure is for many reasons most unlikely: (1) it should differ from the bridge structures of the related aluminium halides³ Al_2X_6 , aluminium dimethylhalides² $\text{Al}_2\text{Me}_4\text{X}_2$, as well as of the boron and probably aluminium hydrides⁴, (2) it cannot be accounted for by any existing valence theory, no forces are available for joining the two AlMe_3 molecules, (3) it requires a shorter interatomic distance (about 2.20 Å) between the equally charged Al atoms than that of a covalent Al-Al linkage (> 2.48 Å), (4) the unstability (non-existence) of a dimer boron trimethyl cannot be explained

Raman spectra favour a bridge structure⁵, but that of type II is excluded by the results of electron diffraction determinations². As shown elsewhere⁶, the stability of B_2H_6 and Al_2H_6 can be accounted for on the basis of the bridge structure⁴ by the formation of B...H hydrogen bonds (of an essentially electrostatic nature) (III). This also allows a bridge structure for Al_2Me_6 , which has not yet been considered (VI). A six-membered ring is formed by Al...H hydrogen bonds. Owing to the inductive electron transfer from the positive Al atom, the negative charge on the H atom should be appreciable. The non-existence of B_2Me_6 can be explained by the much smaller electron transfer from the less-positive B atom, which is not compensated by the expected shorter interatomic distance. Al_2Me_6 is now no exception to the bridge structures of its related aluminium and boron derivatives. This is comparable to the dimer gold dialkyl halides and tetramer cyanides⁷, where one atom (halogen) (IV) and two atoms ($\text{C}\equiv\text{N}$) (V) respectively form the bridge. No new valence theory is required, and the Al-Al distance is now longer than that of a covalent linkage.

It is noteworthy that the distances to be expected for structure VI are in qualitative agreement with the peaks of radial distribution curves derived from electron diffraction determinations, which are 2.07, 2.6, 3.42, 3.93¹ and 2.01, 2.58, 3.3, 4.05 Å respectively². The C-H and Al-C distances within the six-membered ring will be near 1.09 and 2.01 Å respectively, the Al...H distance slightly longer than that of a covalent linkage and not very different from (1.7) 1.8 Å. Making the reasonable assumption that the angles CAIH and AICH in the ring are about 109.5°, the important distances mainly contributing to the radial distribution curve below 4 Å are Al-C 2.01 Å, Al-C' 2.73 Å, Al-H 2.59 Å, Al-Al' 3.22 Å, C-C 3.28 Å, C-C' (both in ring) 3.5 Å, C (in ring)-C (outside ring) 4.0 Å. These distances show a reasonable relationship to the observed peaks. This should justify new quantitative calculations, based on the suggested bridge structure, for testing such model and possibly establishing its actual dimensions.

Mechanism of the Red Cell Changes in Non-hæmolytic Jaundice

CERTAIN characteristic changes are found in the erythrocytes in obstructive jaundice. The red cells are increased in diameter but not in thickness, so that they are relatively flat cells. Associated with this alteration in shape, target cells are seen in the blood in large numbers and the red cells are resistant to hæmolysis by hypotonic saline solutions. The volume of the cells may or may not be increased.

The same changes have been demonstrated in cases of toxic-infective jaundice. Here, in most

instances, the presence of some obstruction to the outflow of bile is indicated by the clinical features of dark urine and pale stools and a positive van den Bergh test in the serum

It has been shown that the changes in the erythrocytes occur as the result of alterations in cells that are already circulating in the blood at the onset of the jaundice, and not because of altered erythropoiesis

The changes in the red cells may be present to a marked degree as early as ten days after the onset of the jaundice. The possibility of this being the result of a new generation of cells is precluded by the fact that erythropoiesis would have to proceed at about ten times the normal rate, and yet no increase in the reticulocytes is seen. Likewise, in recovering cases the blood is restored to normal in as little as ten days, again without signs of rapid cell regeneration

If red cells are transfused into a jaundiced patient, the transfused cells can be shown to take on the characters described above in about a week. Some mechanism, therefore, exists for producing these changes in circulating red cells

The bone marrow in jaundice shows no abnormality that could be responsible for the alterations found in the circulating cells

Detailed analysis of the changes in the chemical constitution of the blood in non-haemolytic jaundice shows that none of these alterations is responsible for the changes in the red cells

It is suggested by comparison with the red-cell changes found after splenectomy that the changes in the erythrocytes in jaundice of the non-haemolytic variety are due to functional disturbance in the circulation of the spleen in jaundice

Changes in circulating erythrocytes in the direction of roundness in cases of haemolytic anaemia have received much prominence in recent years. It is suggested here that the opposite change, flattening, also results from alterations in cells as they circulate in the peripheral blood stream

Siderocyte Levels in 'Normal' Human Beings

FOLLOWING the partial elucidation of the physiological properties of the siderocyte as the normal ageing erythrocyte¹ and in view of pathological studies now in progress, it became desirable to establish 'normal' siderocyte levels in human beings, and to study the effects of sex, age, menstrual cycle, diurnal variation, iron therapy and exercise upon such levels.

Below are summarized the results of such an investigation carried out in the University of Birmingham.

The differences of the means between the age-groups in the female do not at any point attain statistical significance, but the first and last age-groups in the male do attain a significant difference of mean from their neighbouring groups. The difference between the means for the male and female is also significant. Both series, grouped in 0.1 per cent siderocyte-class intervals, approximate fairly well to normal distributions

Daily siderocyte counts throughout two successive menstrual cycles in each of two female subjects showed no cyclical tendency. Hourly siderocyte

AN ANALYSIS OF SIDEROCYTE LEVELS IN 279 'NORMALS' BETWEEN THE AGES OF 5 AND 65 YEARS

Total series

Age group	5-	15-	25-	35-	45-	55-65	All ages
Number of subjects	32	118	46	30	29	24	279

Coefficient of variation	77%	48%	57%	46%	37%	17%	50%
P for diff of successive means	0.15	0.9	0.65	0.65	0.8		

Grand mean Male 0.46, Female 0.54, Difference 0.08 $P = 0.01$

counts on six subjects revealed no evidence of diurnal variation. The exhibition of fairly large doses of ferrous sulphate (up to 1,500 mgm iron daily) for periods up to 21 days did not affect siderocyte levels in four subjects

Moderately severe exercise (sprinting 440 yards) produced no change in level immediately afterwards in each of four subjects, but the injection of small doses of adrenalin, which is without effect on blood *in vitro*, produced an immediate but transient rise of up to 2 per cent, falling to normal in 1½ hours, in six subjects. In our view, this response is probably due to splenic contraction, since Granick² has shown numerous siderocytes in teased spleen preparations.

Siderocytes are thus shown to be normal and constant inhabitants of circulating peripheral blood in normal human beings, there being a slight sex difference in level. For most practical purposes, however, a value of 0.5 ± 0.3 per cent will serve as the 'normal' level for human beings above the age of five years. Higher levels have been reported in infants³, but so far no information is available as to when the level becomes stabilized.

Exercise, iron therapy, and menstruation do not appear to influence the siderocyte levels herein established, nor do they show diurnal variation.

Full details of this investigation will be published elsewhere

Structure and Nutrition of the Cornea, Cartilage and Wharton's Jelly

We have read with great interest the letter by Barcroft *et al.*¹ Barcroft and his co-workers observed the passage of large molecules in Wharton's jelly of the umbilical cord of foetal sheep, and they believe that there exists a non-vascular pathway through which nourishment travels along from the placenta towards the foetus. While there seems to be every justification for this interpretation of the findings, we are of the opinion that this easy and relatively fast passage of large molecules may contribute to the nutrition of Wharton's jelly itself. With a few exceptions² (apart from the large umbilical vessels, which are not supposed to give off nourishment for the surrounding tissues) the substance of the umbilical cord is completely avascular. In this respect Wharton's jelly is closely similar to cartilage and the cornea. It is generally accepted that both cartilage and the cornea are nourished by diffusion from the surrounding tissues, and it seems to us that to assume a similar method of nourishment for Wharton's jelly is entirely justifiable. Both Wharton's jelly and cartilage are rich in two closely related substances, mucotin sulphuric acid and chondroitin sulphuric acid respectively.

Some months ago our attention was directed to the work of Jorpes *et al.*³ describing the presence of heparin in the substantia propria of the human and bovine cornea. This observation was based on the metachromatic staining reaction of the substantia propria corneae after toluidin-blue staining. We repeated this method on sections of rabbit, guinea pig, rat and normal human corneae, and we confirmed the presence of a metachromatic substance. The reaction in the rabbit's cornea, especially after the use of basic lead acetate as a fixing agent, was particularly intense. This staining reaction is strictly confined to the cornea and stops sharply at the corneo-scleral junction. While the real chemical basis of this reaction can be proved only by micro-chemical analysis, it appears justifiable to suppose that the substance responsible for the specific staining reaction is either heparin, which is a mucotin polysulphuric acid, or a chemically allied substance, because only these substances give a metachromatic staining reaction with toluidin-blue.

The presence of metachromatic substances in the substantia propria corneae is not given in standard histological descriptions, although muco-protein was found by Morner⁴ and mucotin sulphuric acid by Levene⁵ after chemical analysis. Krause⁶ in his book on the biochemistry of the eye, referring to the above findings, states that the part played by these acids in such "metabolically inactive" tissue as the substantia propria is not known.

It is of interest that the mast cells, which, according to Jorpes *et al.*³ are responsible for the production and the maintenance of the heparin level of the circulation, give a particularly vigorous metachromatic staining, and consequently the intensity of metachromasia displayed by these chemically related substances can be used within certain limits as a starting point for chemical differentiation.

As previously stated, the cornea derives its main nutrition by diffusion from the margin. We have found numerous mast cells around the capillary loops at the limbus corneae, and we believe that these cells facilitate diffusion and nutrition by maintaining a

high heparin concentration. The translucency of the cornea may also be maintained by and dependent upon the presence of heparin, or some chemically related substance.

The cornea, cartilage and Wharton's jelly are avascular structures, and they all contain similar or closely related metachromatic substances. They all bear the same peculiar relationship to their blood supply, and consequently their nutrition must be similar. Our assumption gains support from the findings of Barcroft *et al.*¹

Finally, it is significant that the cornea is the only tissue with which successful homografting can be carried out, and the explanation may lie in its chemical structure and peculiar nutritional conditions.

Mechanism of Bacterial Flocculation caused by Protozoa

WITHIN the last two or three years several investigators¹⁻⁴ have reported in these columns that certain Protozoa growing in sewage possess the power of causing flocculation of the bacteria on which they feed, a property which is obviously of value to the organisms themselves, since it facilitates the collection of food bacteria, and may also be of importance in sewage purification.

So far as I am aware, the mechanism of this peculiar phenomenon has not been described. In the holotrichous ciliate *Balantrophorus minutus*, the ability of which to cause such flocculation has already been recorded⁵, it has been found that the feeding mechanism involves the production of mucus secreted within the peristome, to which the food bacteria adhere before being ingested, and are thus prevented from being swept out of the peristome by the ciliary currents. This mucus has been found gradually to accumulate in the culture-fluid and, not being a diffusible substance, remains in the neighbourhood of the ciliates themselves. The resulting local increase in the viscosity of the culture medium causes the entanglement and flocculation of the bacteria. When flocula from *Balantrophorus minutus* cultures are examined under the microscope, the bacteria are seen to be cemented together by an amorphous substance which, upon staining with methylene blue with mucicarmine and Delafield's haematoxylin, or with safranin, shows the metachromatic effect characteristic of mucus with these dyes. Control cultures of the same mixed bacterial flora which have not been inoculated with the ciliate show no flocculation, and smears, upon staining, give sharp monochromatic coloration, no matrix being visible between the bacteria.

This matter is dealt with more fully in another publication at present in the press

Effect of Temperature on Fertility of the Male

EXPERIMENTAL work on many mammals, including dogs, rabbits, cats, rams and bulls, has shown that in those species with the testicles enclosed in an external scrotum, there is normally a significant temperature difference between the testicles and the body. This temperature difference varies in different species from 1° to 8° C and is essential for the proper functioning of the testicles. If the temperature of the testicles is artificially raised to body temperature, sperm production is greatly lowered and the animals concerned may to all intents and purposes become sterile. There is, of course, no diminution of desire.

The experiments of Young¹ may be cited as typical of the work which has been carried out on this subject. Young ran hot water (46–47° C) over the testicles of guinea pigs for periods of 15–30 minutes. He found that some degeneration of the germinal epithelium began immediately and that the consequent diminution of fertility was apparent for twelve days.

This knowledge has important practical application in animal breeding. For example, the sterility of a valuable strain of rams in Australia was shown recently to be due to nothing more than a thick growth of wool on the testicles. When this source of warmth was removed, the fertility of the rams was restored. The sterility of an undescended testicle is apparently due to its being kept at body temperature. If the testicle can be massaged down into the scrotum, it produces sperms.

McLeod and Hotchkiss have reported² experiments in this connexion on the human subject. Healthy young men were exposed in a fever cabinet to a temperature of 110° F for a period of 32 minutes. For eighteen days after the experiment, their sperm counts remained at a normal figure of 300–400 million. The counts then fell to as low as 20 million and remained subnormal for sixty-seven days. Medical evidence quoted in the same paper indicates that with a sperm count less than 60 million a man is almost certainly sterile.

No mention was made in McLeod and Hotchkiss's paper of the possible adverse effects of hot baths on mature males. I investigated this important possibility. The matron of a London hospital told me that the temperature of a patient's bath is about 105° F, which is well above body temperature. The temperature of a domestic hot bath is nearer 110° F, the temperature of the fever cabinet experiments. Dr John Hammond, with whom I discussed this problem, is of the opinion that such a temperature might reduce human male fertility. He added the interesting information that the fertility of white men is much reduced in the tropics, and that more native children are conceived there in the cooler months. Dr. John Baker, of the School of Compara-

tive Anatomy, Oxford, has raised the question of the possible adverse effects of hot baths purely on the evidence of work on lower mammals³.

It is not suggested that the hot-bath habit is the sole cause of male infertility, but it would seem to be a fruitful line of research, according closely as it does with the general rise in male infertility, the reduction of the birth-rate in 'civilized' as opposed to backward nations, the greater reduction of the birth-rate in the richer sections of the community and the peculiar fall given to the birth-rate by the present War and the War of 1914–18.

Naturally Occurring Polyesters

MAY I add to the recent note¹ on the isolation of a natural elastic polyester²? The natural occurrence of polyesters was observed as early as 1908 by Bougault and Bourdier³, who showed that the waxes obtained by extraction of the leaves of a variety of conifers are linear polyesters of hydroxy-acids such as juniperic acid (ω -hydroxypalmitic acid) and sabmic acid (ω -hydroxylauric acid). These polyesters, or 'etholides', have average molecular weights of the order 1,000–2,000, and were afterwards shown to have the same general properties as the synthetic polyesters obtained by heating ω -hydroxy-monocarboxylic acids⁴. The average molecular weights of the natural esters show that they belong to the α -polyester type rather than the ω - or linear superpolyester type synthesized by Carothers and Hill⁵. Bougault appreciated the analogy between the etholides on one hand and polysaccharides and polypeptides on the other.

The etholides (natural and synthetic), which are polyesters derived from the self-condensation of ω -monohydroxy-monocarboxylic acids, are to be distinguished from the second class of linear polyesters synthesized by Carothers and Arvin⁶ by the condensation of dihydric alcohols and dicarboxylic acids. The properties of the natural elastic polyester constituting the skin enclosing the seeds of *Smilax rotundifolia* indicate that it is not a linear polyester but that a degree of cross-linking of the polymer chains occurs².

Kemp and Peters suggest that the principal hydrolytic product of the polyester, an acid of the approximate molecular formula $C_{16}H_{32}O_6$, is a trihydroxy-monocarboxylic acid, if this suggestion is correct, the elastic properties of the natural polymer may be reproduced in synthetic polyesters derived from polyhydroxymonocarboxylic acids.

Non-luminous Flame Gases

AFTER flame has travelled through a homogeneous flammable mixture, the gases left behind ('flame uses') rapidly reach what is for all practical purposes state of equilibrium. The flame gases (like ordinary open flames) are in general luminous, and their temperatures as determined by (i) calculation, (ii) fine platinum wires and (iii) quartz-covered platinum wires of the same overall diameter, differ by hundreds of degrees C. Typical temperature measurements made with combustible gas-air mixtures during the re-pressure period in large closed-vessel explosions by means of wires of 0.0005 in diameter are given in the accompanying table. We think that the explanation is that a proportion of the tri-atomic molecules formed during combustion holds in very stable fashion an excess of energy (probably in virtue of abnormal structure), and because of this an abnormal dissociation takes place, the products of which combine on the plain platinum surface^{1,2}.

	Temperatures (°C)	
	28% Carbon monoxide	9% Methane
Calculated	2110	1860
Platinum ..	1790	1680
Quartz	1440	1360

In the special case of inflammable mixtures with a very large excess of combustible gas, the abnormal dissociation appears to be suppressed in the flame gases, for the plain and quartz-covered wires yield exactly the same temperatures. These temperatures are far lower than the calculated temperatures¹, and, of course, the flame gases are luminous. When, however, such mixtures undergo combustion in a tube, the flame gases, although luminous after the early stages of flame-front travel from the igniting spark, suddenly become non-luminous after further travel due apparently to a sudden change in the mode of combustion in the flame front¹. This rather remarkable phenomenon is vividly demonstrated in the flame photograph shown in Fig 1, which was taken on a moving film during the explosion of a mixture (88 per cent carbon monoxide plus 12 per cent oxygen) in a glass tube.

We have recently completed a series of plain and quartz-covered wire temperature measurements with such mixtures in a closed iron tube 12 ft in length and 4 in in internal diameter. The wires were placed axially along the tube at various points up to 20 in from the igniting spark. The results for a mixture (90 per cent carbon monoxide plus 10 per cent oxygen) are shown in Fig 2. It will be seen that when the flame gases are luminous the wire tempera-

tures are more than 200° C. below the calculated temperature, whereas after 15 in (when the flame gases are presumably non-luminous) they are much greater and are nearly equal to the calculated temperature—indeed even more so than appears, for the wire temperatures are given as measured and have not been corrected for radiation loss either from the flame gases or from the wires. It would appear, therefore, that non-luminous flame gases, unlike ordinary flame gases, are just hot normal gases.

It may be of interest to point out that the flame photographs of Bone and Frazer suggest that non-luminous flame gases are also produced immediately after detonation is set up³.

Effect of Length on Tensile Strength

THE results of a large number of tension tests on nominally identical test pieces can conveniently be represented by a frequency curve in which the ordinate gives the frequency of occurrence of test pieces the strength of which is represented by the abscissa. The frequency of occurrence of test pieces the strength of which falls between the limits $x + dx$ and x is given by $f(x)dx$. When the frequency curve is integrated with respect to x and between the limits $-\infty$ and x , an integral curve is obtained the ordinate $F(x)$ of which gives the proportion of test pieces with strength less than x . The proportion of test pieces with strength greater than x is given by $1 - F(x)$. Where the frequency curve does not depart greatly from normality, its characteristics can conveniently be summarized by its mean (μ), standard deviation (σ) and skewness $\sqrt{\beta_1}$.

It is of interest to derive the distribution of strength of rods the length of which differs from those tested. Consider first the strength of rods which are n times as long as those tested.

If the material is statistically homogeneous, such rods can be regarded as being composed of n rods of unit length chosen at random and placed end to end. Fracture will occur when the breaking load of the weakest of the n rods is reached. Owing to the predominance of low results, it would be expected that the mean strength would be lower and that the distribution would be more negatively skew than the distribution for the unit test pieces, and that the standard deviation would be lower. If $F_1(x)$ and $F_n(x)$ are the probability integrals for the strength of test pieces of length 1 and n units respectively, the distribution of the strength of the long test pieces is obtained by calculating the chance that n unit test pieces chosen at random shall all be stronger than a given strength, for this is the chance that the weakest of n test pieces shall exceed the given strength.

Thus $1 - F_n = (1 - F_1)^n$. This result was given by Pierce¹.

Fig 1

Fig 2

DISTRIBUTION PARAMETERS WHEN UNIT CURVE IS NORMAL

The similar problem of determining the distribution of strength of test pieces shorter than the unit test piece does not seem previously to have been treated. Consider each unit test piece as divided up into m equal parts, and consider the distribution of strength which would be expected if each part were tested separately. Each strength figure, which had previously been obtained for the unit test pieces, would again be obtained, and associated with each of these strengths there would be $(m-1)$ results of higher strength.

Owing to the predominance of high results, it would be expected that the mean strength and standard deviation of the distribution of the shorter test pieces would be greater than those of the distribution of the unit test pieces, and that the curve would be positively skew. The probability integral for the short test pieces ($F^{1/m}$) is obtained by stating that the distribution of the least of the strengths of m test pieces taken at random is the same as the distribution of strength of the unit test pieces. Thus

$$\left(1 - F \frac{1}{m}\right)^m = 1 - F_1,$$

$$\text{or } 1 - F \frac{1}{m} = (1 - F_1)^{1/m}$$

It is thus seen that the same formula holds for n less than unity (equal to $1/m$) as for n greater than unity. In the special case in which the distribution of the strength of the unit test pieces is normal, the characteristics of the distribution for other lengths have been computed and are shown in the accompanying curve. For n integral the results given by Tippett² have been used, while for n fractional the results have been worked out using Sheppard's Tables³. Values of the normal distribution beyond the range given in these tables were required and these were evaluated by Sheppard's method. The unit of the ordinates of the curves of σ and μ is the standard deviation of the distribution of strength of the unit test pieces. To obtain the mean strength of test pieces of given length, the appropriate value of μ multiplied by the standard deviation of the unit

distribution must be added to the mean of the unit distribution. From the graph it is seen that both mean and standard deviation increase rapidly for fractional lengths and decrease more gradually for integral lengths. For lengths greater than unity, the distributions are negatively skew, and for lengths less than unity, they are positively skew.

The practical use of these results requires very careful consideration and as it cannot be dealt with briefly, it will form the subject of a report to be published elsewhere.

Entropy of Saturated Liquid-Vapour Mixtures, and Trouton's Rule

It is well known that the entropy of a saturated vapour usually diminishes continually as the saturation temperature and pressure increase up to the critical values. On the other hand, the entropy of the saturated liquid increases continually. At any equilibrium below the critical, the vapour entropy S_v is greater than the critical entropy S_c , while the liquid entropy S_l is less. Thus it is possible to define a mixture of saturated liquid and vapour, say, of dryness q , such that the entropy of the mixture will be equal to the entropy at the critical point. The defining equation will be

$$(1-q)S_l + qS_v = S_c \quad (1)$$

For a number of substances, the value of q so defined varies but little over the whole range from the triple point to the critical point. Thus, for such substances, there is a particular mixture the entropy of which is approximately constant at the critical value. Table 1, obtained by examining tabulated data, shows mixtures the calculated entropies of which differ by no more than 10 per cent from the critical entropy over the whole range of available data, in some cases down to the freezing point, although the vapour and liquid entropies vary widely.

TABLE 1 MIXTURES GIVING APPROXIMATELY CONSTANT ENTROPY

Substance	CH_3Cl	$\text{C}_2\text{Cl}_2\text{F}_2$	CH_2Br_2	NH_3	CO_2	H_2O
q	0.63	0.89	0.29	0.554	0.61	0.50

Consideration of this circumstance has suggested the following discussion of a definable ideal case.

Since $S_v = S_l + \frac{L}{T}$, S_l can be eliminated from equation (1), to give

$$(1-q) \frac{L}{T} = S_v - S_c \quad (2)$$

Now let us imagine an ideal substance such that the equation for the entropy of a perfect gas is applicable to its saturated vapour right up to a critical condition, and also such that its mixture of dryness q has constant entropy equal to the critical value. Then substitution in equation (2) will give the following expression for its heat of vaporization

$$(1 - q) \frac{L}{Rt} = \frac{5}{2} \log \frac{t}{t_c} - \log \frac{p}{p_c} \quad (3)$$

Assuming that real substances may be considered to approach this ideal, we can substitute in equation (3) experimental values of boiling points and heats of evaporation at a given pressure, say, atmospheric, and the critical temperatures and pressures, and so calculate values of q (Table 2)

Substance	He	H ₂	N ₂	O ₂	HCl	Cl ₂	CO ₂	CS ₂
q	0.840	0.745	0.755	0.720	0.715	0.692	0.805	0.735
Substance	C ₆ H ₆	C ₆ H ₅ N	NO	NH ₃	C ₂ H ₅ OH	H ₂ O		
q	0.742	0.741	0.752	0.720	0.768	0.693		

It is immediately obvious from Table 2 that the values of q so calculated are nearly equal for all the substances. The average is 0.746, which is nearly equal to 0.75. This may be of significance, since it gives a whole number ratio, 3/1, of molecules in the vapour phase to molecules in the liquid phase.

Thus a number of real substances behave approximately in such a way that their heats of vaporization and boiling points at atmospheric pressure are related to their critical temperatures and pressures as would be those of an ideal substance having the perfect gas laws for its saturated vapour, and a constant entropy for its mixture containing 3 molecules of vapour to 1 of liquid. The 3/1 ratio may be related to the packing volume of spherical symmetry.

It will be clear that use of this idea, and consequently substituting $q = 0.75$ in equation (3), will predict values of $\frac{L}{t}$, so that the suggestion gives something corresponding to Trouton's rule. But Table 3, which compares experimental values of $\frac{L}{t}$ with values calculated on $q = 0.75$, shows it is more accurate than Trouton's rule.

TABLE 3

Substance	He	H ₂	N ₂	O ₂	HCl	Cl ₂	CO ₂	CS ₂
$\frac{L}{t}$ Expt	5.1	10.8	17.3	18.1	20.7	19.2	31	21

Resolving Power of the Microscope using Polarized Light

In a recent paper¹ I derived formulæ expressing the distribution of light in the geometrical focal plane of optical systems of high relative aperture, and, using these formulæ, curves were given showing the distribution of light in directions perpendicular to, and parallel with, the direction of polarization for a system fulfilling the sine-condition, and of numerical aperture equal to 0.77. A conclusion drawn, on the basis of this work, was "The curves have bearing on the resolving power of microscopes. A variation of the resolution for two fixed points with rotation of the direction of polarization is suggested by them."

A paper has now come to my notice which confirms the existence of such a variation. In "An Application of Polarised Light to Resolution with the Compound Microscope"², Stump refers to a note in Carpenter's "The Microscope and its Revelations" (p. 325, 1891 edition) which records, as an unexplained fact, that by placing a Nicol analysing prism over the eyepiece "the effect [of resolution] is much strengthened". Stump examined a number of objects having minute periodic structure, and "it was found that in all cases where the prism was set so as to pass light vibrating in a plane parallel to the striæ being shown a clearer image was formed than when the prism was not used". This is fully in accord with the results I obtained mathematically, of which there seems possible a simple physical explanation.

In the diagram, HB is the direction of vibration of the light vectors in the incident plane-polarized wave, and $ABCD$ is an annulus of the emergent converging spherical wave. Elements of the wave passing through A, B, C, D proceed to the focus at O along the ray-paths AO, BO, CO, DO . At O the disturbances associated with A, B, C, D are E_A, E_B, E_C, E_D , of which E_A, E_C have full effect whereas E_D, E_B cancel along the direction HO , and along the direction of E_A, E_C have effective magnitudes $E_D \cos \delta$ and $E_B \cos \delta$, where δ is the angular semi-aperture of the annulus $ABCD$. Thus, relative to the meridian HC , the effective amplitude along HB is attenuated, and in the direction HC there is a greater concentration of energy in the outer part of the wave. This state of affairs leads to a narrower diameter of the Airy disk in the direction HC , and a (relatively) broader diameter in the direction HE . That is, striæ with their lengths in the direction HE will be better resolved than those along HC .

Evidently the resolution with the prism in its position of maximum effect will be greater than that using non-polarized light. This was found to be the case by Stump (*loc cit*): "a clearer image of the striæ was formed than when the prism was not used".

Stump attempted a very inadequate and tentative explanation of the phenomenon, and urged the use of as many separate beams as there were structural elements—claiming that the final image "would then be a composite, formed by the blending of several independent images, each showing some particular element in the structure". A photograph of the surface structure of *Amphipleura pellucida* is given in support of the claim.

BACTERIOSTATIC EFFECTS OF POTASSIUM CHLORATE ON SOIL NITRIFICATION

By DR. H. LEES

AND

DR. J. H. QUASTEL, F.R.S.

From the Agricultural Research Council Unit of Soil Metabolism*

IN the course of studies on the kinetics of soil nitrification, using our perfusion technique¹, we have observed a remarkable inhibitory effect of potassium chlorate on the conversion of ammonia into nitrate. We propose briefly to describe some of our main findings concerning the effects of chlorate on this important metabolic process in soil.

Technique

Our technique consists in perfusing a column of soil with oxygenated fluid by a circulatory process. The fluid, which contains in solution the substances the metabolism of which is being investigated, is made to percolate through the soil into a flask where it is mixed and aerated, and whence it is made to drain again through the same soil. The process is continuous and may be maintained for an indefinite period. The soil is left intact throughout the experiment and analyses are made only on the soil perfusate. The rate of perfusion is such that no water-logging of the soil takes place. The soil is well aerated and experiments in which oxygen is substituted for air have shown that aeration of the soil is, under our normal experimental conditions, optimal for nitrification.

The kinetics of metabolic events in the soil may be accurately studied by this technique, since it ensures constancy of oxygen supply and water content throughout the soil. The temperature is kept constant at 70° F by thermostatic control. Substances, the effects of which on the course of soil nitrification are being studied, can be added to the perfusion fluid at any time in the experimental period without handling or disturbance of the soil, and the subsequent rates of nitrification can be accurately measured.

The soil is, in fact, treated throughout the experiment as a biological whole, every effort being made to ensure constancy of the environment in which the soil is exercising its metabolic changes, except in so far as changes in the environment are brought about by the products of metabolism.

The soil is usually air-dried at room temperature and sieved. The fraction 4-1 mm is found convenient for perfusion purposes, and although any quantities may be used, depending upon the nature of the experiment, we have usually used 30-50 gm. in these studies.

Effects of Potassium Chlorate on the Velocities of Nitrite and Nitrate Formation in Soil

When ammonium sulphate solution is perfused through a soil, nitrification commences after an initial lag period, and nitrate accumulates until all the ammonia has been utilized. Traces of nitrite also appear in the early stages but disappear again as nitrification proceeds. When, however, a mixture

7	2	44	55	2	57	46

of ammonium sulphate and potassium chlorate is perfused through soil, nitrite accumulates instead of nitrate. The sum of the nitrite and nitrate, formed by the ammonia oxidized, is only slightly affected by the chlorate when this is used in relatively small concentrations. Typical results are shown in Table 1. They show that chlorate exercises a specific inhibitory influence on the conversion of nitrite into nitrate, and that the mechanisms concerned with the initial oxidation of ammonia are practically unaffected. The results also supply direct proof that oxidation of ammonia in soil to nitrate proceeds *via* the intermediate formation of nitrite. While few have seriously doubted that nitrite is an intermediate in this process, the evidence so far has been indirect and could not be regarded as supplying satisfactory proof of the essential intermediate role of nitrite.

Effects of Potassium Chlorate on Nitrite Oxidation in Soil

When sodium nitrite is perfused through soil, rapid oxidation to nitrate takes place after an initial lag period due presumably to the slow development of nitrite-oxidizing organisms in the soil. The presence of chlorate at so low a concentration as $M \times 10^{-6}$ markedly inhibits the process. Typical results are given in Table 2, which show that sensible inhibitory effects occur with $2.5 \times 10^{-6} M$ chlorate.

TABLE 2. RATES OF NITRITE OXIDATION ON PERFUSION OF 200 ML OF $M/280$ SODIUM NITRITE SOLUTION THROUGH 30 GM OF GARDEN SOIL IN THE PRESENCE AND ABSENCE OF POTASSIUM CHLORATE. INITIAL VALUE OF NITRITE $N = 333 \gamma$ /GM SOIL

Effects of Potassium Chlorate, at Low Concentrations, on Ammonia Oxidation

Perfusion of ammonium sulphate through the soil in presence of very small concentrations of potassium chlorate has given results which show that although nitrite accumulates, it disappears in time. This disappearance is apparently not due to destruction of chlorate, because chemical and biological tests have indicated that chlorate is still present when nitrite oxidation has been completed. This phenomenon of nitrite accumulation is shown in Fig. 1. It will be observed (from Curves 4 and 5) that when relatively high concentrations of nitrite are formed, a long

* At Rothamsted Experimental Station, Harpenden.

Fig 1 EFFECT OF POTASSIUM CHLORATE ON NITRIFICATION OF 200 ML $M/200$ AMMONIUM SULPHATE BY 30 GM OF ALLOTMENT SOIL. Conc of potassium chlorate present: Curves 1, nil, 2, $M/540,000$, 3, $M/180,000$, 4, $M/60,000$, 5, $M/20,000$

latent period of about fourteen days elapses before the nitrite disappears. After this period the rate of nitrite oxidation is normal. Since chlorate is still circulating at the end of the experiment, it follows that the oxidation of nitrite takes place in spite of the presence of the chlorate.

This result is consistent with the view that the chlorate does not markedly retard the actual chemical process of nitrite oxidation in the soil to nitrate, but rather that it inhibits the proliferation of those cells responsible for this oxidation. The initial burst of nitrite formation is due to the fact that the development of the ammonia-oxidizing organisms is unaffected by the chlorate, whereas that of the nitrite-oxidizing organisms is very greatly reduced. The latter do, however, develop slowly, presumably during the long latent period, until sufficient cells are produced to account for the final fast phase of nitrite oxidation.

It is, in fact, characteristic of the action of chlorate that it causes an initial lag, of variable duration, in

Fig. 2. NITRITE OXIDATION IN THE PRESENCE OF $M/10,000$ CHLORATE (FRESH SOIL)

the rate of oxidation of nitrite. This is seen in the results given in Fig 2, which show the rates of nitrite oxidation, in presence and absence of chlorate, on perfusion of $M/280$ sodium nitrite solution through soil. That the nitrite is completely oxidized to nitrate has been verified by analyses of the perfusion fluid. It is noteworthy that the rate of nitrite oxidation in presence of chlorate, after the initial long lag period, approximates to that obtained in the absence of chlorate.

Effects of Chlorate on a Soil Enriched with Nitrite-Oxidizing Organisms

If the view is correct that chlorate exercises its inhibitory effect largely by retarding the proliferation of nitrite-oxidizing organisms and not by poisoning the oxidative mechanism involved in nitrite utilization, it follows that chlorate should not prevent nitrite oxidation in a soil which has been enriched with the appropriate organism.

For experiment, soils were perfused with water alone and with sodium nitrite solution containing 50 γ of nitrite nitrogen per ml for four days (until the

Fig 3 INITIAL PERFUSION ---, WATER, —, NITRITE, — —, CHLORATE SECOND PERFUSION ●, NITRITE ALONE, ○, NITRITE PLUS $M/10,000$ CHLORATE

nitrite was completely utilized). After this period the perfusion fluids were changed, the soils were thoroughly washed with water and re-perfused with fresh solutions of sodium nitrite, with and without the addition of potassium chlorate. The velocities of nitrite disappearance were measured and are shown in Fig 3. They show that chlorate exercises a small inhibition of the rate of nitrite oxidation in a previously nitrite-perfused soil, but that there is no initial lag period in the rate of nitrite disappearance. The same phenomenon occurs with soil previously perfused with water, though the subsequent rates of nitrite utilization are somewhat less. These results are consistent with the view that nitrite perfusion in a soil (in absence of chlorate) enriches it with nitrite-oxidizing organisms, which can then bring about their oxidations even in the presence of chlorate. Water perfusion of a soil results in a similar (though smaller) enrichment of these organisms owing to the fact either that traces of undecomposed nitrites are present in the soils, or that nitrite is being formed from the nitrogenous matter still in soil. A soil, however, initially perfused with chlorate (and cor-

Fig 4 NITRITE OXIDATION IN THE PRESENCE OF CHLORATE (SOIL ENRICHED WITH NITRITE OXIDIZING ORGANISMS)

taining therefore but few nitrite-oxidizing organisms) shows on subsequent perfusion with nitrite a lengthy time lag before the nitrite undergoes oxidative change (see Fig 3).

Rate of Nitrite Oxidation in Soil in Presence of Chlorate

It would be expected that if the main effect of chlorate, at low concentrations, is to prevent proliferation of nitrite-oxidizing organisms, the velocity of nitrite oxidation in a soil enriched with these organisms would be a constant in the presence of chlorate. The velocity would be proportional to the number of cells initially present, it would not increase with time, in the presence of chlorate, as it should if proliferation were taking place.

The results of four separate experiments are included in the data given in Fig 4, in which the nitrite content of the perfusion fluid at any moment is plotted against time. The soils were enriched with nitrite-oxidizing organisms by initial perfusion with sodium nitrite, and then they were perfused with $M/280$ sodium nitrite solution containing potassium chlorate. Three concentrations of chlorate, $M/10,000$, $M/20,000$, $M/40,000$, were used, but much the same results were obtained with all three.

Fig 4 should be a straight line if the velocity of nitrite oxidation is constant. It will be seen that there is a close approximation to linearity, indicating the largely bacteriostatic action of chlorate.

TABLE 3 RATES OF NITRITE OXIDATION ON PERFUSION OF 200 ML $M/280$ SODIUM NITRITE CONTAINING $M/2000$ POTASSIUM CHLORATE THROUGH 50 GM GARDEN SOIL, IN THE PRESENCE AND ABSENCE OF NITRATES

Effects of Nitrate on Chlorate Bacteriostasis

The action of chlorate in inhibiting the oxidation of nitrite in soil is partially or completely eliminated by the presence of nitrate. If a solution of sodium nitrite containing potassium chlorate is perfused through soil containing initially a relatively high concentration of nitrate, little or no retardation of nitrite oxidation is exhibited. Results given in Table 3 show how increasing concentrations of sodium nitrate in the perfusion fluid have increasingly large effects in neutralizing the action of chlorate.

This result demonstrates that nitrate alleviates the bacteriostatic effect of chlorate. The effect of nitrate is apparently specific, for no such alleviation is accomplished by phosphate, borate, chloride, sulphate, arsenate or *p*-aminobenzoate.

This phenomenon is possibly related to that described by Crafts² and by Hurd-Karrer³ in which nitrate reduces the toxicity of chlorate to plants.

Experiments are now being carried out to discover how nitrate exercises its neutralizing effects on chlorate inhibition.

Summary

Potassium chlorate at low concentrations ($c M \times 10^{-5}$ to $M \times 10^{-6}$) exercises a bacteriostatic action on soil organisms oxidizing nitrite to nitrate. The effect is specific, as chlorate at these concentrations has little or no effect on the conversion in soil of ammonia into nitrite. Chlorate administration to a nitrifying soil thus results in nitrite accumulation. Chlorate has little or no effect on nitrite oxidation in a soil which is rich in nitrite-oxidizing organisms. Its effect at low concentrations seems almost wholly concerned with the inhibition of the proliferation of these micro-organisms.

The bacteriostatic action of chlorate is specifically neutralized by the presence of nitrate, the alleviating action of which increases with its concentration.

WAR-TIME MEDICAL PROGRESS IN AMERICA

"ONE of the memorable experiences of this war," writes Prof D W Bronk, in his contribution to the symposium on war-time advances in medicine held by the American Philosophical Society (*Proc Amer Phil Soc*, 88, 151, 1944), "is to stand at evening in the Great Court of Trinity College, Cambridge, outside Isaac Newton's rooms, and watch the Flying Forts return." More memorable, some Cambridge residents might add, was the unforgettable sight, sudden and wonderful after dark years of trial, of the sky one summer evening full of the aeroplanes and men going out on the first one-thousand bomber attack. Such developments have been made possible by the work, in Great Britain and in the United States, of men like Prof Bronk, who is professor of biophysics at the University of Pennsylvania and co-ordinator of research, Office of the Air Surgeon, Headquarters Army Air Forces. His contribution to this symposium discusses such human problems of aviation as the effects of rising, as modern fliers do, to heights of six miles in six minutes, the effects of high-speed manoeuvres in machines built to withstand the stresses involved (although the human body is not) and problems of night flying and vision.

such problems could no doubt be classified under heading of environmental effects, and Colonel F Doriot, of the Quartermaster Corps, shows in other article how profoundly these affect the soldier and the sailor. He points out, also, that we are all concerned with protection from the environment. Clothing, he thinks, has been largely developed for the purpose of dressing the shop window and not for the particular tasks of the wearers. His discussion, illustrated by diagrams, of the problems posed by the clothing and equipment of the soldier and sailor, who have to operate in many different climates and have to be able to withstand rapid changes from one set of external conditions to other, has many applications to civilian life. The fighting man needs flexible clothing which is either warm or cool as the conditions demand. Colonel Doriot pleads for more technical education in the scientific principles of rational clothing than those engaged in the textile and clothing industries get at present, in this respect they compare unfavourably, he suggests, with a number of other industries. Fundamental researches are required. To neglect only one detail, Colonel Doriot rightly considers the problem of boots of great importance, and this point is also emphasized by Prof E A Strecker, of the University of Pennsylvania, in his article on neuropsychiatry. The foundations of morale, Prof Strecker says, are simple and obvious things, such as satisfactory living conditions, good, appetizing and well-cooked food, comfortable and nice-looking uniforms and, above all, easy-fitting shoes. Sport and diversion are also important. His discussion of war, which can, he says, no more be suppressed than the heart-beat can be stilled, is full of common sense. Important for those at home is his statement that morale fell when soldiers heard of strikes in the coal and other industries.

Another problem of the environment is discussed by Prof J L Gamble, of Harvard Medical School, in his article on the water requirements of castaways, a subject which has been much studied in Great Britain as well as in the United States (see, for example, MacDonald Critchley's Bradshaw Lecture on "Shipwreck Survivors" (London J and A Churchill, 1943) and the work sponsored by the Medical Research Council Committee on the Care of Shipwrecked Personnel). Assessing the water requirement during fasting with little or no physical activity at about 100 c.c., Prof Gamble describes experiments which indicate that at least 100 c.c. of this can be replaced by glucose or other food sugars or starches, with all the physiological advantages of this replacement, without disturbing the water balance. There was no appreciable water gain in subjects who drank 100 c.c. of sea water every day (3-4 litres would be needed to cover the daily water requirement of a castaway and even 500-600 c.c. would cause disturbing effects). In these subjects extracellular fluid volume was conserved by the gain from sea water and by increased withdrawal from intracellular water. Experiments done near Cape Cod in hot weather indicated that periodic immersion or wet clothing completely prevented loss of water above the basal rate. Solar radiation without a breeze caused loss of water at ten times the basal rate (more than 2 litres were thus lost by one subject, who, in six hours, thus wasted enough water to cover his intake need for three days). Shade, periodic immersion and wet clothing completely prevented this. Most impressive of all was the protection from water loss afforded

by a breeze (fortunately rarely absent). The castaway's great risk is therefore hot, windless weather.

Dr E J Cohn, of Harvard Medical School, contributes a valuable article on blood, blood derivatives and blood substitutes, with a bibliography of forty-eight references, mostly American. The contents of this paper can only be briefly indicated. It discusses plasma proteins, the dimensions in Angstrom units of these proteins and those of suggested blood substitutes, the equilibrium between the albumins and globulins of plasma and the tissues, the dissociation of the globulin molecules of plasma, the separation and concentration into fractions of the plasma albumins and globulins and their stability when separated. The article also discusses the use of gamma globulin antibodies for the prevention of measles and of iso-haemagglutinins in the typing of blood. The remarkable properties which the long, rod-shaped molecules of fibrin confer on fibrin films, made from fibrinogen and thrombin, are described. These films can be used as substitutes for the dura mater in neurosurgery of the brain. Their mechanical properties recall those of plastics, they can, for example, be stretched to twice or three times their original length or made into seamless tubing. Fibrin foam, made also from thrombin and human fibrinogen, may be, when it is dry, of two types. One type is light, fluffy and highly compressible, it wets easily, losing 90 per cent of its dry volume by shrinkage. The other type is dense, firm and less compressible, it wets slowly and then loses only about 50 per cent of its dry volume. Fibrin foam is used for stopping bleeding from veins or oozing surfaces, but not for stopping arterial haemorrhage, it is useful in neurosurgery. By appropriate control of their preparation, other types of fibrin-clot can be made, some of which are used in surgery or for skin-grafting.

Prof C S Keefer, of Boston University School of Medicine, deals with the use of penicillin in the treatment of various bacterial infections, and Prof A O Whipple, of Columbia University, also discusses this substance, together with others, in his article on recent advances in the treatment of wounds. R E Dyer, assistant surgeon-general, United States Public Health Service, writes about immunology. He directs attention to recent improvements in the immunizing potency of typhoid vaccine and the discovery and improvement of vaccines against yellow fever and typhus fever and of tetanus toxoid. Compulsory use of tetanus toxoid has removed the menace of tetanus from the United States military and naval forces, we are informed that tetanus is, for the same reason, no longer a menace to British fighting men. Further improvements in these and other immunizing procedures may be expected before long.

Perhaps the most thought-provoking article in the symposium is that contributed by Prof R J Dubos, the discoverer of gramicidin. Drug therapy, he argues—and many experienced observers will agree with him—constitutes only one facet of the complex problem of infection, and we should not be led away from these other aspects by the spectacular and popular appeal of recent chemotherapeutic achievements. Our difficulty is not to prepare more and more antibacterial substances, but to find out how they act in the body. They do not act as gross protoplasmic poisons, but selectively inhibit some vital process in the parasite's life. We need much more work on the problem of how they act.

There have been, on the other hand, important epidemiological and immunological advances towards

the control of such serious diseases as smallpox, yellow fever, diphtheria and infestations with such animal parasites as the hookworms and the schistosomes. We should study the host-parasite relationship much more, including micro-organisms among the parasites, and get away from the rather narrow channels into which the very rapidity of the success of serological and immunological research has directed investigation. The whole picture should be studied by resuming broad biological and biochemical studies of the host and its bacterial and animal parasites. So far as the bacteria are concerned, the study of the complex property of parasites which we call virulence is important. A given parasite can cause epidemics or disease only when it has been able (1) to reach a susceptible host, (2) to overcome the cellular and humoral defences of that host, (3) to multiply in it, and (4) to damage it. Each of these factors can vary independently of the others. In order to cause an epidemic, the parasite must possess them all at the same time. A highly pathogenic strain of hæmolytic streptococci, for example, may have only a low degree of communicability, and the converse may be true of other strains. The study of the resistance of the host is likewise very important, and there are other factors which the epidemiologist must consider. Prof. Dubos believes that we shall eventually be able to predict the course of epidemics and to organize 'listening posts' which will detect qualitative and quantitative changes in the number of infectious agents and in those of their properties which affect their virulence. A beginning in this direction has already been made.

It is a matter for conjecture, Prof. Dubos considers, whether preventive chemotherapy will ever become advisable or effective, but preventive immunological treatment can certainly be effective, as immunization against smallpox, typhoid, diphtheria and other diseases has shown. High degrees of immunity produced by means of killed bacterial cultures are, however, very specific and do not protect against related organisms of another immunological type, so that type-specific immunity protects against only the particular organisms concerned. For this reason, effective immunization of whole populations with type-specific vaccines may be impossible. It is, nevertheless, possible in some instances, for example, the pneumococci, to direct the immune response against a component of the bacterial cell which is common to all types of pneumococci. Possibly bacterial cell components will be found in all bacterial groups which can be attacked in this way, so that we may eventually be able to immunize against all the types of each group. The non-specific immunization of this kind which has so far been achieved is, however, lower than that produced by type-specific vaccines, but more research into it might enable us to raise its potency. We have hitherto studied type-specific immunization almost exclusively. Immunization techniques, moreover, have been up to now primitive in their principle of killing the pathogenic organism with heat or antiseptics. It is certain that a very large percentage of the material injected in anti-typhoid vaccination has no immunological value at all and even causes unfavourable reactions in those to whom it is given. It is very important to isolate the chemical components of the cell which do produce the immunity. If we could do this, we might, in the distant future, prepare artificially the substances required to produce the immunity.

G LAPAGE

ORGANIZATION OF INDUSTRIAL RESEARCH

FUTURE historians will no doubt record that opening decades of the twentieth century were characterized by the beginning of a systematic application of the results of scientific research to everyday life and the consequent foundation of research organizations, both large and small, mainly devoted to the best utilization of new knowledge in the service of commerce and industry. Moreover, these organizations, staffed by professional research workers together with technicians and other assistants in considerable numbers, stood out in striking contrast to the research conditions of the days of Faraday, Joule and Kelvin, when even advanced technological research was an entirely private venture. It is often forgotten to-day how young in years organized industrial research really is, and that while there are certain industries, such as heavy chemical and electrical engineering, which have expanded on a vast scale with laboratories widely distributed over Great Britain, there are also other industries, deeply rooted in history, having as yet no medium for the exploration of fresh ideas and wholly dependent on traditional techniques.

At a meeting of the London Branch of the Institute of Physics on February 17, Dr R. E. Slade, speaking from a wide practical experience, dealt with the factors which he regards as essential to the successful organization of research in the laboratories of manufacturing firms where most industrial research is now done.

Dr Slade began by pointing out that the laboratory must be a well-run unit constituting an integral part of the firm's activities and in full sympathy with the industry which it is trying to serve. Research is admittedly an individualistic operation, and its success is not a mere question of organization, though organization can facilitate the performance of the work, for this reason, the director or research manager should himself be an experienced researcher, able to inspire the workers under him, but suited to his methods to the personalities of the various section leaders. "There is room in every laboratory for a scientifically trained organizer to do the administrative work for the director, so as to relieve him of as much administrative work as possible." The ideal chemical research laboratory would thus consist of a director and an administrator with six section leaders, five having charge of researches and the sixth looking after services including the library, analytical department and workshop. Probably the most efficient size of industrial chemical laboratory would have six to a hundred university-trained workers and up to four hundred other workers. There is always a tendency for a laboratory to increase in size, but while it is cheaper to allow this rather than start a second new laboratory, it is not advisable to let the laboratory become so big that the director cannot know all his men and be prevented from exercising his personal influence and encouragement. "Not only do we want laboratories with distinctly different outlooks, but we want in each laboratory men with different kinds of training who will look at problems in different ways and tackle them in different ways too."

Dr Slade does not believe that the direction of a laboratory can be carried out effectively by a committee, he admitted the utility of advisory panels, but

phasized that the success of the laboratory depends upon the director being a research worker, capable of directing the laboratory, and having also the capacity of making a committee believe that it is directing the work when he is in reality leaving it to the common sense and ability of the section leaders. Moreover, if a company is to gain full value from its research department, there must be a director on the board of management who knows what research ought to do for it, and this director should himself have had research experience.

Industry must be alive to developments which may take place in any of the sciences, for example, the chemical industry needs to employ mathematicians, physicists, metallurgists and biologists. In regard to physicists, it would seem that they have not in the past been used to full advantage, for they have often been engaged as narrowly specialized technicians such as X-ray crystallographers and spectroscopists, instead of being given the opportunity of examining industrial problems in their entirety and so determining how best physical knowledge may be applied and what factor needs to be measured and to what degree. Similarly, the metallurgist should not be brought in, for example, when pipes have already corroded and broken down, but should be given the opportunity to see that industry has pipes that will stand up to manufacturing conditions.

One of the great problems of present-day industrial research lies in the difficulty of acquiring new specialized techniques as they appear. No laboratory is big enough to keep a specialist in every possible technique, and so workers have to be sent to the originator of the technique as students. This method is too slow for industry, and Dr Slade thinks that a national central laboratory of scientific techniques should be set up to serve industry in this field.

The cost of research is £1,500-£3,000 per annum per university-trained research worker employed, including assistants, mechanics, glass-blowers and services. Though high, the cost is fully justified by the results. Those carrying out research should have some authority to purchase equipment up to a reasonable sum, otherwise absurd cases will occur where men earning perhaps £600 a year or more are kept on unimportant work for weeks while a committee decides whether to spend £60 on a piece of apparatus.

Great importance should be attached to the linking of the research laboratory to the utilization of the products by the consumer, hence the director should learn to look at his problems from the point of view of the production manager and of the sales manager, and orient some of his researches accordingly.

After referring to the way in which the thirty research associations of Great Britain assist the special industries to which they are attached, Dr Slade then described in detail a method of linking research and industry, as carried out at the Mellon Institute in America, where manufacturers may have a specific piece of work carried out by endowing a fellowship for a number of years, in this way valuable work has been done on such diverse materials as limestone products, furs and their by-products, plastics, solvents, pesticides, rosins, high-boiling products, etc.

It is not in general desirable for university departments to carry out technological research, though industry has obtained its scientific outlook from the

men it has recruited from the universities, and while important discoveries may be made in industrial laboratories, we shall always be dependent upon the universities for the most fundamental work and for new ideas, so nothing should be permitted to limit this vital function of the universities.

Dr Slade concluded by stating that research thrives in an atmosphere of freedom, enthusiasm and achievement, and the aim of the organization of industrial research should be that of creating the best conditions for the individual workers with the view of applying knowledge and research to improve the arts of industry.

A particularly vigorous discussion followed the address, from which the following points, expressed perhaps in somewhat disjointed form, may be noted. Many good men are lost to research through promotion to administration. The researcher should have knowledge of what is practically possible in the craft of his industry, industry is suffering because problems are not being dealt with on a large enough scale, and there is need for co-operative research on a bold and comprehensive plan. Pooling of ideas will not result in lack of competition. A spirit of national service is requisite for industry in peace-time as well as in war-time. Workers should not be handicapped by having to write regular detailed reports of their work while it is in progress, but it is better to write a comprehensive report at the end. The cost of development and advertisement of results is bound to be relatively high in relation to the cost of the original research, it has therefore been suggested that exploratory research be limited by allocating, say, 20 per cent of research grants to original work and 80 per cent to development. The workshop is vital in research laboratories, and all workers should be able to carry out certain simple operations themselves and be able to make sketches of new apparatus, though very complicated drawings may be left to a draughtsman. Several speakers, including Dr Slade, deplored any suggestion that a central committee should decide what fundamental work each laboratory should undertake, though the opposite view was also expressed that in the interests of humanity some direction should be given as to what are socially desirable researches.

H LOWERY

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Saturday, March 3

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W 1), at 2.30 p.m.—Annual General Meeting. Mr A. S. Kennard "The Early Digs in Kent's Hole, Torquay, and Mrs Cazalet" (Presidential Address).

Monday, March 5

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S W 7), at 5 p.m.—Mr J. M. Wordie "North-West Greenland and North Baffin Island" (Kodachrome Film).

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p.m.—Mr D. Tiranti "The Need for Administrative Engineering".

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N W 3), at 7.45 p.m.—Mr E. A. Roth "Technical and Economic Problems of Post-War Agrarian Policy in Central Europe".

Tuesday, March 6

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W C 1), at 1.30 p.m.—Dr S. A. Huza'ayim "Further Light on the Upper Palaeolithic of Egypt".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5.15 p.m.—Sir Henry Dale, O.M., Pres. R.S. "Nerve Endings and Chemical Transmitters", (1) "Actions of Involuntary Nerves and of Substances which Mimic or Paralyse their Effects".

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (in the small Physics Theatre, Imperial College of Science, Prince Consort Road, South Kensington, London, S W 7), at 5 30 p m—Prof. G. I. Finch, F.R.S. "Electron Diffraction"

SHEFFIELD METALLURGICAL ASSOCIATION (at 193 West Street, Sheffield 1), at 6 30 p m—Dr L. Northcott and Mr D. McLean "The Influence of Centrifugal Casting upon the Structure and Properties of Steel"

Wednesday, March 7

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1 45 p m—Mr R. F. Wilson "Colour as a Factor in Industrial Design"

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W 1), at 2 30 p m—Mr Henry W. Robinson "Robert Hooke and the Importance of his Work in Medicine and Biology"

ROYAL ENTOMOLOGICAL SOCIETY OF LONDON (at 41 Queen's Gate, South Kensington, London, S W 7), at 3 30 p m—Dr W. E. Ripper "Recent Advances in the Control of Agricultural Pests"

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Dr K. R. Sturley "Frequency Modulation"

Thursday, March 8

LINNEAN SOCIETY OF LONDON (joint meeting with the Zoological Society of London) (at Burlington House, Piccadilly, London, W 1), at 2 30 p m—Mr G. O. K. Sainsbury Photograph of a remarkable specimen of *Pseudopanax crassifolium* C. Koch—an Adult Tree with a Reversionary Shoot on the Trunk at 2 50 p m—Prof. J. McLean Thompson "The Study of Plant-Behaviourism: A Common Meeting-ground for future enquiries by Morphologists, Geneticists, Anatomists, Systematists and Physiologists Alike"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 15 p m—Sir Lawrence Bragg, F.R.S. "Some Physical Problems of the Solid State"

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Mr L. S. Atkinson "Modern Electric Lift Practice"

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S W 1), at 6 30 p m—Mr C. G. Woodford "Electrics for Aircraft"

Friday, March 9

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S W 1), at 10 30 a m—Conference on Surface Finish (A series of twelve Short Papers in five Groups: Group 1, Physical Aspects; Group 2, Methods of Measurement and Representation; Group 3, Considerations of Rational Specification and Requirement in Surface Finish; Group 4, Production Methods and Results of Modern Practice; Group 5, Effect of Surface Finish on Production)

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 3 15 p m—Annual General Meeting, at 4 p m—Mr S. Ernest Melling "Water and Water Supplies" (Presidential Address)

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 4 30 p m—Scientific Papers

PHYSICAL SOCIETY (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S W 7), at 5 p m—Mr W. R. Ballard "The Formation of Metal-sprayed Deposits" Mr R. F. Bishop, Mr R. Hill and Prof. N. F. Mott, F.R.S. "The Theory of Indentation and Hardness Tests"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p m—Prof. David Brunt, F.R.S. "Climate and Human Comfort"

Saturday, March 10

INSTITUTE OF PHYSICS (SOUTH WALES BRANCH) (in the Physics Department, University College, Swansea), at 2 30 p m—Inaugural Meeting Dr C. Sykes "Physics in Metallurgy"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Municipal Offices, Town Hall Street, Blackpool (endorsed 'Borough Electrical Engineer') (March 10)

ASSISTANT TEACHER OF MATHEMATICS at the School of Building, East Ham Technical College—The Chief Education Officer, Education Department (T), Town Hall Annex, Barking Road, East Ham, London, E 6 (March 10)

RESEARCH ENGINEER immediately to organize and control Laboratory and Experimental Department of progressive manufacturing company situated in N.W. London area—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No. C 2482 XA) (March 12)

FOOD AND DRUG ANALYST for service with large Company operating in the Middle East—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No. F 2894 XA) (March 12)

TEACHER OF ELECTRICAL ENGINEERING SUBJECTS, a TEACHER OF MECHANICAL ENGINEERING SUBJECTS, a TEACHER OF MATHEMATICS, and a TEACHER OF CHEMISTRY (to teach PHYSICAL and INORGANIC CHEMISTRY to Honours Degree standard)—The Principal, Acton Technical College, High Street, Acton, London, W 3 (March 12)

SENIOR (Reference No. C 2485 A) and JUNIOR (Reference No. C 2486 A) ENGINEERS (mechanical and electrical) to carry out work of national importance in a Government Department (location London)—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting the appropriate Reference No. (March 16)

SUPERVISORS (PRODUCTION ENGINEERS, 3) for TELEGRAPH WORKSHOPS at Calcutta, Jubbulpore and Bombay, for manufacture of stor connected with Telecommunication Development—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No. C 2484 A) (March 17)

ADDITIONAL OFFICER for Secretarial and Organizing work (applicant should be chemists with organizing and administrative ability)—The Hon. Secretary and Registrar, British Association of Chemists, 1, Piccadilly, London, W 1 (endorsed 'Additional Officer') (March 31)

GARDEN STEWARD (woman) with responsibility for the upkeep of about 50 acres of gardens and grounds—The Secretary, Girton College Cambridge (April 10)

MALE TECHNICIAN, with some knowledge of section cutting and staining, for Anatomy Department—The Secretary, Medical School St. Thomas's Hospital, London, S E 1

EDUCATIONAL PSYCHOLOGIST—The Director of Education, County Hall, Kendal, Westmorland

GRADUATE IN BIOLOGY (candidates must be able to teach CHEMISTRY and PHYSICS in relation to BIOLOGY and HYGIENE) at the Folkestone Day Technical School for Girls—The District Secretary, Kent Education Committee, at the Technical Institute, Ashford, Kent

REHABILITATION OF EUROPEAN CULTURE

THE encouraging measure of agreement reached by Mr Winston Churchill, President Roosevelt and Marshal Stalin at the Yalta meeting, as indicated in the communique issued on February 12, goes far to offset some of the doubts as to common policy which have arisen since the tentative proposals of the Dumbarton Oaks Conference were issued last October. Agreement has been reached on the difficult question of voting procedure in the Security Council of the new peace organization, and a Conference of the United Nations is to be called to meet at San Francisco on April 25, 1945, to prepare the charter of such an organization along the lines proposed at Dumbarton Oaks.

The declaration on liberated Europe is the most important of the three parts into which, apart from the military plans, the statement falls naturally. It is true that European policy cannot be sharply separated from the treatment of Germany, but without some common European policy and without the reconstruction of civil life and the full restoration of social, economic and cultural activity, in which science has a prominent place along with other intellectual activities, there can be no hope of any adequate solution of the German problem.

That problem will probably provide the most searching if not necessarily the first test of the adequacy of any new world organization, and it is the appearance of lack of harmony in the policy of Great Britain, of the United States and of the U.S.S.R. towards the liberated countries of Europe during the last six months, that has given such a shock to public opinion. The three Governments—and the statement expresses the hope that the provisional Government of the French Republic may be associated with the three Powers in the procedure suggested—declare their mutual agreement to concert their policies, during the temporary period of instability in liberated Europe, in assisting the peoples of Europe to solve by democratic means their pressing political and economic problems. The establishment of order in Europe and the rebuilding of national economic life must be achieved by processes which will enable the liberated peoples to destroy the last vestiges of Nazism and Fascism and to create democratic institutions of their own choice. To foster the conditions in which the liberated peoples may exercise their sovereign rights and self-government, the three Governments pledge themselves to give joint assistance where required, in their judgment, to establish conditions of peace; to carry out emergency measures for the relief of distressed peoples, to form interim Government authorities broadly representative of all democratic elements in the population and pledged to the earliest possible establishment through free elections of Governments responsive to the will of the people, and to facilitate, where necessary, the holding of such elections.

The declaration, which provides for consultation

with the other United Nations in Europe when matters of direct interest to themselves are under consideration, thus proposes to proceed from world order to peace, and though it may be objected that there are areas in Europe which are not yet ripe for democratic institutions, over a large part of liberated Europe this implementation of democracy should be effective and appropriate. Further, the second proposal—emergency measures for the relief of distressed peoples—is one that may well at once provide an effective means of education in democratic methods and the touchstone of the sincerity and determination of the three Great Powers subscribing to the Yalta Declaration.

There is in fact no question touched upon during the recent conference that is of more immediate concern to Great Britain than that of relief for the liberated countries of Europe. Grave anxiety regarding the relief of France has already found expression in the House of Commons and in the Press, and has not been dispelled by either Mr. C. R. Attlee's statement or the more recent one of Mr. Richard Law. The concern is shared by the troops serving on the Continent, and on all sides there is evidence that a more generous, imaginative and positive policy would be welcomed, and indeed is essential if the goodwill we found on the Continent is not to run to seed. The criticism of, and charges of grave weaknesses in, the United Nations Relief and Rehabilitation Administration which Dr. H. V. Evatt, leader of the Australian delegation, uttered at the opening session of the Conference of that body at Lapstone are in keeping with growing uneasiness which has been apparent since its council met at Montreal in September.

Much of the criticism that has been levelled against the United Nations Relief and Rehabilitation Administration may in fact be unjustified, for since the first session of its council met at Atlantic City in November 1943, a large organization has been built up and much information gathered about the needs to be met and the supplies available to meet them. So far, however, the actual relief work in the liberated areas of Western Europe has been done by the military authorities in conjunction with the French and Belgian Governments. Dr. Evatt argued from this that it was doubtful whether the Administration would perform all the duties intended under the terms of its charter, and urged that there must not be the same delays in the Far East that have occurred in Europe. Further, he said that administration was over-centralized and that wider national representation was needed at all levels of the administration and staff.

It is expected that U.N.R.R.A. may shortly be allowed to send supplementary supplies to certain countries; such as France, Belgium and Holland. This will involve a complete departure from the general principle of that body, that it will not operate in a country until invited to do so by the Government in power, and, in Western European countries who wish to pay for their supplies, until the relevant financial negotiations have been completed. While

the new proposal releases the organization from the strictures that have in the past prevented it from dealing promptly with emergencies, it in no way affects the general schemes for providing relief in bulk in accordance with the original terms of the charter.

Though it is clearly unfair to blame U.N.R.R.A. itself for the present position, even given the limitations on its activities imposed by its charter, public opinion is not disposed to hold the Government entirely free from blame in this matter. Mr. Richard Law's statement in the House of Commons on February 13 with reference to relief appeals for allied and liberated countries will not allay misgivings on this point, for it showed lack of insight and imagination. His statement on February 14 on the economic and supply position in the liberated countries of Western Europe, while satisfactory so far as it went, did not remove the impression that the military authorities, to whom the matter had been left, have not shown sufficient foresight. The main failure, Mr. Law said, has been in distribution, but the national governments cannot be held entirely responsible because not only were the means of transport lacking but also the administrative machine had become seriously impaired and had to be rebuilt. No one will deny that the first objective of the military authorities must be to wage war and to wage war effectively, or that the requirements of our liberated allies are in direct competition with urgent military demands. Equally it cannot be denied that the position is one where high policy is also involved, and where the Government cannot evade the responsibility for rapid and decisive action.

What appear to be lacking are the imagination and warmth of sympathy already evident in public opinion. There is in the Government's statements no appreciation of what might be the effect of announcing that we were to release, for example, some of our own ample stocks of fats for France and Belgium, where the deficiency is so great. It is not yet forgotten in Europe that Mr. Churchill, when Secretary of State for War in 1919, not only opposed the continuance of the blockade of Central Europe as endangering a collapse of the entire structure of German social and national life, but also had earlier sought on Armistice Day to send six food ships to Hamburg. It is all a matter of the right priorities. We have large reserves of many other foodstuffs which were regarded as essential when the climax of the War still seemed distant but which could be safely reduced now. Even a reduction of food rations in Britain might be considered for the critical few weeks, provided that the urgency were explained fully to the people.

What is most essential is a clear understanding of how dangerous the alienation of France may become, and of how urgent it is not merely to meet the need but also to seize the chance to restore France. When that is realized there can be no hesitation over the decisions to be taken to divert transport from the more obvious military needs to the more urgent but no less vital needs of the political and economic

warfare against the same enemy. Here, as throughout the War, has been the weakest spot in our strategy, the rapid reconstruction of Europe is in fact not merely the background against which all relief work, whether through the United Nations Relief and Rehabilitation Administration or not, should be viewed, but also an essential condition of victory, without which military success may be sterile.

Nor should it be imagined that relief and reconstruction have physical or material aspects alone. The reconstruction of France and of Europe is a cultural and spiritual task also. Even now, six months or more after the liberation of France and Belgium, cultural contacts have scarcely been established except in the most desultory manner. Import of French books has not yet been resumed, and the Government's own policy with regard to paper for books removes all hope at present of providing France with the British scientific and other books which she awaits. Without such interchange and collaboration there cannot come the full understanding between the two great Western democracies which must be a prelude to their closer co-operation in the reconstruction of Europe, in whatever form that may ultimately take.

The abatement of national prejudice and passion, and the mutual sacrifices which are involved in building any form of world order, will not be made in moments of sentimental impulse. They will arise out of a clear understanding of what is involved and the deliberate surrender of the lesser to the greater ideal. That is the substance of Prof. D. Mitrany's argument in "The Road to Security"*. He sees the only basis of security in positive and constructive action in the social and economic fields. An international organization cannot limit itself to the negative purpose of restraining aggression in a world of change; it must also help to bring about constructive change.

Prof. Mitrany, in this little pamphlet, brings out very clearly the relation between national planning and world order. International peace cannot be considered as consisting only in the prevention of violence. We must take account of social unity and economic development, and it was the failure to do this that broke the system of common order represented by the League of Nations. If once more we conceive of security as merely a matter of policing the world against the use of violence, we may well find divisions in the economic world—competition in shipping and aviation, for raw materials and trade—even more acute than during the twenty years of truce. Even the aspirations for full employment and social security, with the national planning and State action involved, may threaten security unless national planning is geared from the outset to international planning.

In fact, the organization envisaged at Dumbarton Oaks will be futile, Prof. Mitrany believes, unless we develop joint economic arrangements sufficiently

comprehensive and far-reaching to prevent a split between the participating Powers. Such arrangements would go far towards protecting States, especially the economically weak States, from economic aggression, and remove the temptation to try aggression for economic and social ends. Moreover, certain agencies are already available for that purpose, as Prof. Mitrany points out, and as is further indicated in the P.E.P. broadsheets which have been brought together and re-issued under the title "Building Peace out of War". Economic technical agencies would be preventive, by their very nature, in a way in which military agencies never can be. Just as it would be their function to give service wherever it is needed, so it would be their duty to deny service where it is not obviously needed and might be abused.

Stress is laid by Prof. Mitrany on this withdrawal of services as an effective form of sanctions, but the most important point is undoubtedly that they are a step towards dealing jointly and resolutely with the very springs of war. The real problem of security and the task of statesmanship are not to keep the nations peacefully apart, but to bring them actively together, and in such a task science has an essential part to play. As is pointed out in the P.E.P. broadsheets, in building European unity, parallel with the establishment of a framework of order and security must go the reconstruction and development of European life in the direction of a social, economic and cultural community which all its citizens have a common interest in maintaining and furthering, and to which all will eventually come to feel a loyalty commensurate with their loyalty to their own countries. Moreover, the key to the restoration of social stability will be the rebuilding and development in new forms of those cultural and other institutions and associations which are the life-blood of a free community, but have been persecuted or suppressed by totalitarian Germany—universities, churches, trade unions, professional organizations, the free Press and radio.

Linked with the rebuilding of institutions is the gradual development of individual leaders in every sphere, and here the emphasis must be on individuals, not governments, for in a Europe functioning as a community the individual leaders of industries, trade unions, universities and other vital institutions are as important as those of regional governments. In such a process the universities of Europe, which inherit the tradition of European unity, must take a central role, whether or not there is linked to them, as is suggested by P.E.P., as centres of post-graduate training and research, one or more special European staff colleges for the training of Europe's key administrative personnel.

There can be no doubt that, as is stated in the final study of this volume, the people of war-ravaged Europe will look to Britain for help and guidance in picking up again the scattered threads of the European tradition, and in rebuilding the institutions in which it is largely embedded. But since that broadsheet was written in 1943, the problem and the task have

* *The Road to Security*. By Prof. David Mitrany. Pp. 20. (Nat. Peace Council, 144 Southampton Row, London, W.C.1, 1944.) 4d.

become urgent and imperative. The situation is desperate, and it is no longer merely a matter of urging that the advance of science demands the resumption of normal free communication and contact the moment military exigencies permit. It is rather that unless the physical task of relief and reconstruction is undertaken forthwith, military success may be sterile. Even now the physical task demands all the help and inspiration it can draw from the cultural life and the institutions which enshrine the tradition of European unity and the highest ideals of its intellectual and spiritual life.

It is in fact a moral obligation that rests on scientific workers to press for the re-establishment of contacts with their colleagues in liberated Europe, and to co-operate with them in building up once more the tradition and institutions of learning and research which Germany has sought to extirpate. The task of reconstructing the universities of Europe is immense, and in the physical sphere little may yet be practicable. But already the planning of such reconstruction is an urgent task, and a generous response to the desperate needs of Europe on the part of scientific workers, no less than of other men of learning and culture, might have an immense effect in establishing an atmosphere of understanding and goodwill and in giving new hope. What are required above all are vision and imagination to sense the possibilities, as well as the dangers, and to grasp the significance of the European cultural contacts and institutions which the Committee on Intellectual Co-operation once represented, not merely in providing the leaders required to-morrow, or in establishing the freedom of thought, of utterance and of investigation, but in creating that sense of European community of interest, of confidence, which brings fresh hope, in place of frustration or despair, and without which the sore-pressed peoples of Europe might have no heart to address themselves to that task of reconstruction.

BOTANY IN BRITAIN

British Botanists

By John Gilmour (Britain in Pictures Series)
Pp 48+8 plates (London: Wm Collins, Sons and Co., Ltd., 1944) 4s 6d net

THE history of science has for so long been written from the point of view of chemistry and physics, with generous recognition of astronomy and even geology, but with almost complete indifference to biology in any form, that it is encouraging to note the recent development of interest in the records of early botanists and zoologists. A brief and accurate history of British botany, written with the knowledge that the late Dr. Gunther on one side and Dr. Agnes Arber on the other have made available to us, is a very valuable help to such development. Mr. John Gilmour's book is excellent and timely.

To survey a history which covers four such changeful centuries, to tell the story of so large and so varied a succession of students, to keep a sense of proportion so that the outstanding developments of the science are not lost in a mass of detail, and to present the story with all its human interest and

charm and excitement as a fascinating adventure, this fourfold task Mr. Gilmour has discharged with eminent success. There are inevitably gaps, particularly perhaps in the early stages of the story: the present reviewer would plead for recognition of Thomas Penny, the friend of De l'Obel and De l'Ecluse and chief author of the "Theatrum Insectorum", and of Thomas Willisel, the first professional field-naturalist, employed by Merret and then by the Royal Society, and the discoverer of many of our rarer plants, particularly in the Pennines and Teesdale. But to compress the record into forty-eight pages, many of them half-filled with pictures, is necessarily to cut it down to the barest skeleton. That Mr. Gilmour has nevertheless found room for such delightful descriptions as that of Stephen Hales' Sunday at Teddington and for clear hints as to the relationship between botanical studies and the general ideas and culture of the time is proof of real skill as a writer as well as of real knowledge as a historian. We notice only one slip in matter of fact: Bilson, not Bilster, is the name of John Goodyer's employer on p. 13.

The book, like others of the series, is almost lavishly illustrated, and here too Mr. Gilmour has chosen his pictures with discrimination. They cover a very wide range of subjects, are representative of different aspects and moments of the story, and thus are a real contribution to the record.

It is much to be hoped that Mr. Gilmour will carry on with work in this field. There is no satisfactory history of botany, and few subjects supply more abundant and more interesting material. He has evidently got a thorough knowledge of very much of what is generally available, and possesses the threefold qualification—a thorough knowledge of botany, an understanding of historical method and research, and the power to write vividly and accurately. We hope that the success of this small essay will encourage him to a large-scale work.

C. E. RAVEN

REJUVENATION OF PLANT GEOGRAPHY

Foundations of Plant Geography

By Prof. Stanley A. Cam. Pp. xiv+556 (New York and London: Harper and Brothers, 1944) 5 dollars

IN a recent review of "Historical Plant Geography" by the late Prof. E. V. Wulff¹, reasons were given for thinking that the subject had been revitalized by the recent application to it of methods and information developed and acquired in other scientific fields. It now appears that while these changes were leading Prof. Wulff to write his book in Leningrad, they had, in the United States, caused Dr. S. A. Cam similarly to set about accumulating material for this comprehensive volume on "Foundations of Plant Geography".

Though both works convey the indication of the opening of a wide territory for scientific investigation, they differ considerably in scope and emphasis. Prof. Cam's book is conspicuous for its reference to a very large body of work by the great American phytogeographers, such as Asa Gray, Fernald, Marie Victorin and Gleason, with their very numerous and able followers. One cannot indeed help the reflexion that the North American continent has offered, and still does offer, greater advantages to the plant

geographer than any other continental area. The circumstance was long ago pointed out that the mountain-range direction from north to south did not hinder the great vegetational movements made under compulsion of the climatic shifts of the Ice Age, and there now persists a tremendously rich flora distributed in patterns the meaning of which we at last begin to glimpse.

Among the most striking resolutions achieved so far we may mention (1) the per-glacial survival of species described by Fernald in the Gaspé peninsula and equivalent areas, (2) the work of Miss Lucy M. Braun to demonstrate the preservation of Tertiary mixed forest in the southern Appalachians, and the differentiation and migration of later vegetation types therefrom, (3) the history of migration and evolution of the genus *Vernonia* in the south and east of the United States worked out by Gleason, and (4) the remarkable history of western American forest types established by Chaney and Mason from fossil and distributional evidence throughout the Cenozoic period.

Nowhere has the study of genetics and its application to the problems of the mechanism of speciation been given more enthusiastic attention than in the United States, and Dr Cam's book is characterized (in contrast with that of Prof Wulff) by a sustained attempt to clarify the relation between modern cytogenetics, evolutionary theory and problems of plant distribution, indeed, about half the book is occupied by discussion of topics in this field. It is evident that the phenomena of speciation are so distinctly concerned with genetic isolation, which itself is closely correlated with geographic isolation, that progress in knowledge of evolution and of phyto-geography alike demands an increasingly critical investigation of the distributional data of plant populations. The recognition of this situation makes great demands (as it presents great opportunities) to the modern plant geographer. He may not assume that the 'species' of taxonomists, his chief working material, are by any means equivalent in status or origin, he must not assume that the first-described species type is necessarily the basic form from which later-described varieties are derivative, and he must always be prepared to submit his collected material to intensive genetic and cytological analysis.

The way in which Dr. Cam attempts to integrate the cytogenetic approach with recent knowledge of geological and climatic history can be illustrated by a quotation (p 432) "In such a region, especially after glacial recession has commenced, there are numerous new, variable and closely associated habitats in which populations of a variety of species can live in rather close proximity. The result of this intermingling of species may be the production of hybrids, followed sometimes by amphidiploidy. With continued glacial recession, the polyploids and backcrosses are in a position to expand their area tremendously. Some of the diploids also may extend far on to the glacial plain, but most of them will probably have only limited expansion. The chances of such polyploids spreading into unglaciated territory to any considerable extent seems unlikely because penetration of closed communities is more difficult."

The reality of such a mechanism as this remains to be established, like that of so many hypotheses for similar distributional and evolutionary situations; but it will be apparent how usefully the book directs attention to the considerable progress recently made in definition of problems and recognition of new approaches.

We may note a few incidental features of general interest which indicate the progress of phyto-geographic ideas in the last decade or two. General opinion is shown to have swung over (partly as a result of the teaching of Willis) from regarding endemics as relict, to regarding them in many instances as recently evolved, it is now said that "some geographers believe in the efficacy of long-distance dispersal for many types of organisms, but the weight of evidence in most cases seems to be strongly opposed to such an assumption"; centres of preservation of plants throughout the ice age are freely accepted to have occurred even in northern territories.

Prof Cam is well aware that in attempting to synthesize the results of many sciences he lays himself open to attack from the specialists in all of them. We shall here only give a single general and constructive criticism. It is stressed that there is necessity for migration of biotypes into new areas if there is to be reasonable chance for new ecotypes to arise. Geographers and ecologists may easily overlook that the habitat may, so to say, migrate to the species, rather than the other way round. By this I mean that we should view plant populations, not as living under stable conditions, but against a background pattern of ceaseless climatic change, with small seasonal shifts at one end of the scale of frequency and amplitude, and glacial epochs at the other. Especially if this alteration affects a topographically varied territory, there is then little need to invoke migration to precede the differentiation of ecotypes.

The section headings will convey the content of the book (1) Introduction, (2) Palaeoecology, (3) Areogeography (that is, distribution patterns), (4) Evolution and Plant Geography, (5) Significance of Polyploidy in Plant Geography. There are an immense bibliography and a useful glossary.

H. GODWIN.

MEASUREMENT OF COLOUR

The Measurement of Colour

By Dr W. D. Wright Pp vii+223. (London: Adam Hilger, Ltd, 1944) 30s. net.

A BOOK by Dr W. D. Wright may confidently be expected to be first class, and the present publication is ample justification for such a prophecy. Colorimetry depends mainly upon classical physics for most of its theory, and luckily the conceptions involved are to some extent quasi-mechanical, which is probably the reason why applications to industry and technology have been both rapid and successful. The reviewer's task may thus best be implemented by discussing some of the more important of these developments in the light of the guidance afforded by the volume before us. Before so doing, however, there are a few features of wider significance. One is the way in which the fundamental character of certain optical instruments and processes is laid bare; for example, the additive trichromatic colorimeter, the photo-electric tricolorimeter and the three-colour process of colour reproduction. The reader can see from the diagrams exactly what functions must be fulfilled, unmolested by photographs or descriptions of particular types of apparatus. Incidentally, what searching examination questions these topics would provide to describe simply and directly the necessary and sufficient conditions that the required ends

(often very involved) may be achieved. It would certainly not be easy to do it better than it is done here. Something of the kind found a place in the best German books of the nineteen-twenties, but they lacked the stimulus to deep comprehension on the reader's part which Dr Wright has managed to introduce.

Another question treated with unusual clarity is that of the human retina, especially from the point of view of Polyak's work (1941). This leads naturally to a comparison of the wave-length and relative luminosity positions of the scotopic (low brightness) and photopic (high brightness) curves, the former for rod (monochrome) vision, and the latter for cone (coloured) vision. Artists and the like are well aware, empirically, of the darkening of red surfaces with diminishing illumination, a species of Purkinje effect for which the relative displacement of the scotopic curve towards higher frequencies is responsible. Although perhaps not directly concerned, psychologists will read this portion with interest, since implicit in these energy relations is supposedly the nature of the connexion between 'fact' and 'correlate'. It may well be that the useful, though problematical, concept of isomorphy will be unable to stand up in its present form against increasingly exact knowledge of retinal reactions. There are other complications, no doubt, but a better biophysics of colour-vision is evidently on the way.

Now for some of the applications. Many industrial matters demand the fixing of minute colour differences rather than absolute 'norms'. The Hardy spectrophotometer is excellent here, since much of the work may be concerned with reflexion, where the accuracy is most favourable. I have witnessed Hardy's machine at work upon reflectance measurements of specially prepared artists' pigments. Even allowing for somewhat elaborate calibration and checking, the speed at which the curves could be constructed was remarkable. As Dr Wright points out, one must not cavil at Hardy's inability to cope perfectly with fluorescence or specular reflexion, since these troubles are inseparable from the system. Nevertheless, the latter component can now be wholly included or wholly excluded, thus removing uncertainty. It is characteristic of the author's practical attitude that he adds a number of methods, more or less approximate, applicable to cases where complete spectrophotometry would not be justified. Much can be done by these means, so long as the absorption wave-length curve does not change direction too abruptly.

A chapter is devoted to colour atlases. These common adjuncts clearly suffer from the disadvantages of being incapable of supplying more than a fraction of all discernibly different colours and, moreover, they fade and get dirty. Nevertheless, they have their uses, as Dr Wright explains. An interesting forecast is that we might "in, say a hundred years' time", be able to do our colour matching and selection by means of the tristimulus values, X , Y , Z , alone. Meanwhile, we are driven by some psychological urge to ask for a pattern, transient as it may be. Musicians say they can appreciate perfectly a melody by reading the score, it is hard to see why artists should not do likewise some day, and obtain colour-harmony from the appropriate algebra.

Several other intriguing outlets for colorimetry follow: chemicals and their mixture, lighting, agriculture, pulp, paper and paint, signal glasses, photoelasticity and so on. In fact, their name is legion, and as if to practise what is preached, several excellent

coloured charts are included, some quite novel, and all of them helpful.

The price is the crux: for what is little more than a manual, thirty shillings does seem excessive. One would like to imagine a student reading this book time and time again, but if he does, he will probably have had to borrow a copy from somebody else.

F. IAN G. RAWLINS.

INTERACTIONS OF HEREDITY AND ENVIRONMENT

Livestock Improvement

In Relation to Heredity and Environment. By Dr J. E. Nichols. Pp vii+208+7 plates. (Edinburgh and London: Oliver and Boyd, 1944.) 10s 6d net.

THIS book, as the author says, attempts to outline the principles and to indicate how the genetic and environmental concepts are interwoven in the idea of livestock improvement. Much original work is included in the book, especially work on problems of sheep-breeding drawn from personal observations in many different countries.

In addition to an outline of the principles and details of genetics as applied to the breeding of farm animals, other factors closely linked with genetics and affecting livestock improvement are dealt with—such as environmental aspects, type and environment, and breed construction. These latter chapters indicate some of the problems which the applied animal breeder as distinct from the pure geneticist has to take into account. Here the idea of evolution as distinct from the modern analytical aspects of genetics creeps in, and the facts given may provide a means of bridging the gap between the ideas of Darwin and of Mendel, or between those of Lysenko and Vavilov. In particular, Nichols' conception of the stratification of the sheep industry in time and space provides the palaeontologist and zoologist with a concrete example of what has occurred, and is occurring, in the evolution of a species, or in the evolution of the fauna in a district. The agriculturalist's aim to control and change environmental conditions is from the zoologist's point of view a grand experiment in the evolution of animals. Throughout the book there is a number of references to work done in tropical countries, these should provide a basis for the development of the animal industry in British Colonies and other tropical countries.

The chapters on gene and character, frequency, inbreeding, outbreeding and hybrid vigour, and performance and progeny testing should prove most useful to the practical breeder of livestock, as they will enable him to see how the modern science of genetics can be usefully employed to effect a short cut to his objectives. The formulae given in several places may prove somewhat difficult to practical breeders, but they are reduced to the minimum that is necessary for proper comprehension by a student of the subject.

The book is packed with information concerning farm animals, well illustrated and has an extensive list of references to which the reader can go for further details. With government policy giving encouragement to the better breeding of farm animals, this book should meet a widespread demand from students, teachers and breeders for more information on the methods of livestock improvement.

JOHN HAMMOND.

CAUSALITY OR INDETERMINISM?

By PROF. H. T. H. PIAGGIO

University College, Nottingham

A SHORT article published in *Nature* of July 22, 1944¹, entitled "Collapse of Determinism", contained a brief statement of von Neumann's claim to have demonstrated that the results of the quantum theory cannot be obtained by averaging any exact causal laws. If one may judge from the number of communications referring to this point which have been submitted to the Editors, many regard this claim with suspicion and desire a more detailed discussion of the grounds on which it is based. Mr. W. W. Barkas² suggested that the existence of statistical regularity when large numbers of events are considered is incompatible with indeterminism, and that if the final result of the behaviour of a million photons were fixed, the behaviour of the first 999,000 must influence the other 1,000. Prof. (now Sir Edmund) Whittaker³ replied that it might be profitable to consider the behaviour of tossed coins. He asked, in particular, whether the statistical regularity for this case, calculated by the ordinary theory of probability, involves the assumption of 'crypto-determinism' (that is, real determinism hidden by lack of detailed information) or merely the assumption of symmetry. This reply produced further letters, too numerous for the Editors to publish in full, and I have been asked to give a connected account of the points raised. I shall start with the experimental evidence concerning coin-tossing, and contrast it with the theoretical discussion. After this I shall touch upon similar considerations for the kinetic theory of gases. Finally, and most important, I shall give some details of von Neumann's supposed disproof of causality, and give the arguments for and against it.

Buffon, the French naturalist, tossed a coin until he obtained 2,048 heads. The results were quoted by De Morgan⁴, who gave also an account of three similar experiments by his own pupils or correspondents. The arrangement by which the last toss ended with a head gave a small advantage to heads, but too small to make any significant difference. Much more extensive experiments, on somewhat different lines, were carried out by W. S. Jevons⁵, who took "a handful of ten coins, usually shillings", and tossed the ten together. He made two series of 1,024 such tossings of ten coins, so that in each series 10,240 coins were tossed. The results of these six experiments were as follows:

No of heads	2,048	2,048	2,048	2,048	5,222	5,131
No of tails	1,992	2,044	2,020	2,069	5,018	5,109
Total	4,040	4,092	4,068	4,117	10,240	10,240
Excess of heads over mean	28	2	14	-10.5	102	11
Proportion of heads	0.5069	0.5005	0.5034	0.4974	0.5100	0.5011
Excess over mean	0.0069	0.0005	0.0034	-0.0026	0.0100	0.0011

If we examine these results, we see that it is easy to misinterpret the meaning of 'statistical regularity'. It is certainly not true, as some correspondents seemed to think, that the numbers of heads and tails are bound to be equal. In fact, the divergence from the mean actually increased from a maximum of 28 in the first four experiments, each based on roughly 4,096 tosses, to a maximum of 102 in the last pair, each based on 10,240 tosses. This is quite in accordance with theory, which, assuming that the probability of a head in one toss is 0.5, deduces that for

a large number n of tosses, it is as likely as not that the divergence from the expected mean $n/2$ will exceed $0.3372\sqrt{n}$, but it is almost certain (99.73 per cent probability) that it will be less than $1.5\sqrt{n}$. For $n = 4,096$ the 'as-likely-as-not divergence' is, to the nearest integer, 22, and the 'scarcely-ever divergence' is 96. For $n = 10,240$, the corresponding numbers are 34 and 152. Thus the actual divergences, though larger and more one-sided than some might have expected, are quite compatible with the theory. But the phrase 'statistical regularity' really refers to the proportion of heads, which, according to theory, should be very nearly 0.5, with an 'as-likely-as-not divergence' of $0.3372\sqrt{n}$ and a 'scarcely-ever divergence' of $1.5\sqrt{n}$. Both these divergences diminish indefinitely as n increases. We may also estimate the theoretical divergence of the proportion by its root-mean-square or 'standard deviation'. This has the value $0.5/\sqrt{n}$, a result which we shall contrast later with Heisenberg's Principle of Uncertainty.

We now come to an important criticism of the theory of probability on which the above calculations are based. As pointed out by Lieut.-Colonel E. Gold⁶, there is an assumption of symmetry, not only in the two faces of the coin, but also in the actions of the hand that tosses the coin. When the hand was replaced by a machine, such as that devised by J. Horzelski⁷, the absence of this symmetry was manifest. By a certain adjustment of the pressure actuating a lever, he obtained 98 heads out of 100 tosses. He then slightly altered the pressure, keeping the head, as before, initially upwards on the machine, and obtained only one head in the next 100 tosses. In this case the tossing mechanism is not a hidden parameter, but is visible and definite, whereas in the usual tossing it is indefinite and, so far as we can manage it, symmetrically distributed. It is possible that the excess of heads in Jevons's experiments was due to some slight lack of symmetry in his tossing conditions. Whether this was so or not, it appears obvious that the description of reality given by the theory of probability in coin-tossing is not complete.

It is therefore erroneous to suppose that the properties of a perfectly normal distribution must necessarily correspond exactly with physical reality, however useful they may be in giving a good approximation to the facts. We cannot disprove the existence of the details of the projection merely by claiming that they upset the purity of the normal distribution. It is rather the very purity of that distribution which goes beyond the physical facts, and so is not a complete description of reality. Similar considerations apply to the kinetic theory of gases, but in this case the symmetry assumed in the theory⁸ is a much closer approximation to the actual facts. But it is only an approximation, and here, as elsewhere in classical physics, pure statistical aggregates do not exist.

This brings us to the question whether such aggregates exist in non-classical physics, in particular in quantum mechanics. We shall examine von Neumann's arguments, using for this purpose not only his well-known treatise "Mathematische Grundlagen der Quantenmechanik" (1932), but also the shorter account, in English, that he gave in Warsaw⁹ in 1937, and the discussion that ensued. The starting point is an analysis of the qualitative laws obeyed by the mathematical 'hypermaximal projective' operators which correspond to the physical quantities occurring in quantum mechanics. Everything is said to be based on six laws, of which two seem more

important than the rest. One is the principle of superposition, extended to quantities not necessarily simultaneously measurable. The other may be called the principle of exact functional correspondence, for example, if an operator represents a physical quantity, then the square of the operator represents the square of the quantity.

In my opinion, however, the emphasis on these simple laws conceals the fact that other conditions of greater importance are imposed by the definition of 'hypermaximal projective' operators. This definition implies some characteristic results of quantum mechanics, and the simple laws are merely the final requirements. Von Neumann shows that aggregates are of two kinds, 'pure' and 'mixed'. The essential property of a pure aggregate is that it cannot be regarded as a mixture of two other non-identical aggregates. The qualitative laws of quantum mechanics show that the aggregates concerned must be pure, whereas all aggregates based upon causal laws, such as tossed coins or gas particles, must be mixed. Hence, he concludes, causality is incompatible with quantum mechanics, and the process of averaging causal laws, as applied in the kinetic theory of gases, cannot possibly be extended to quantum mechanics. There is no need, he says, to go more deeply into the details of a supposed system which is governed by further conditions ('hidden parameters') in addition to the wave functions. These hidden parameters would upset the qualitative laws of quantum mechanics. He admits that quantum mechanics in its present form is certainly defective, and, in spite of its great success in explaining physical phenomena, may possibly, in the long run, turn out to be false. But this is true of every theory, we can never say that it is proved by experiment, but only that it is the best summing up of experiment at present known.

Von Neumann therefore concludes that there is at present no reason and no excuse for supposing the existence of causality in quantum mechanics. This conclusion is described by Whittaker⁹ as not only novel and unexpected, but also almost incredible, yet he endorses it with the exultant declaration "the bonds of necessity have been broken, for certain classes of phenomena, crypto-determinism is definitely disproved".

Other comments have been more sceptical. At the Warsaw conference, the president, C. Bialobrzelski, after hearing von Neumann, admitted the validity of the argument that it was impossible to fit causality into the framework of quantum mechanics, but expressed a doubt as to the logical coherence of that framework. In his opinion it is deficient because it does not take account of irreversible changes, and also because, in certain conditions of measurement, the indeterminism of the final state disappears, and the assumptions of discontinuity and indeterminism do not correspond to reality. He thought it necessary to introduce a new postulate concerning measurement. At a later meeting of the same conference a letter from Heisenberg said that the quantum theory, in its present form, could not yet give a logically coherent account of nuclear physics or of cosmic rays.

Many critics are suspicious of purely abstract arguments which make no reference to experiment. Of course, such experiments as those of Davison and Germer on electron diffraction and of Condon and Gurney on radioactivity, though excellent as illustrations of the Uncertainty Principle, yet have no value in deciding whether this uncertainty is due only to

lack of detailed knowledge, or to true indeterminism. On a somewhat different plane is the argument of Whittaker⁹, who, though a supporter of von Neumann, illustrates his argument by a reference to the passage of plane-polarized light passing through a Nicol prism, and shows that the phenomena cannot be explained by causal laws governing any hidden parameters attributed to the photons. However, H. Pelzer¹⁰ gives two models in which hidden parameters, attributed at least partly to the Nicol prism, can exist and obey causal laws. From this he infers that the arguments of Whittaker and von Neumann are incomplete, even though he agrees with their conclusion that quantum phenomena are truly indeterminate.

My own criticism of von Neumann is founded upon a paper by A. Einstein, B. Podolsky and N. Rosen¹¹. By considering the problem of making predictions concerning a system on the basis of measurements made on another system which had previously interacted with it, they conclude that *the description of reality as given by a wave function is not complete*. As a wave function is a mathematical way of representing a probability distribution, this conclusion is almost exactly the same as that which I enunciated concerning coin-tossing. I therefore, with great diffidence, offer the opinion that the existence of causality has *not* been disproved. It is true that Einstein's opinion has been rejected by N. Bohr¹², but there are other grounds for supporting it. In fact, the postulate of quantum mechanics that electrons cannot be distinguished from one another appears, at least to me, not to be a statement that Nature is incomprehensible, but merely that quantum mechanics is incomplete. However, I do not wish to insist that there is no difference between coin-tossing and quantum mechanics. One striking difference is that in coin-tossing the standard deviation of the proportion of heads depends only upon the number of tosses, and can be diminished indefinitely, but in quantum mechanics the Principle of Uncertainty gives for the product of the standard deviations of the momentum and displacement a minimum value, namely, $h/4\pi$. The occurrence of Planck's constant in this result seems to show that there is something essentially new. I should find it easier to accept von Neumann's conclusions if his arguments, instead of being purely qualitative, contained this constant. Perhaps it is really concealed somewhere in the background, like a hidden parameter.¹

To conclude, I will quote the opinion expressed by Bertrand Russell¹³ in 1936, that at present there is no decisive reason in favour of complete determinism (causality) in physics, but that there is no reason against it, and that it is theoretically impossible that there should be any such reason. But Russell does not mention von Neumann's arguments. My own conclusion is that the balance of the present evidence is rather against complete causality, but that the question is still unsettled.

CONSTRUCTION OF THE SHOOT APEX IN CEREALS AND OTHER GRASSES

By DR. B C SHARMAN

Botany Department, The University, Leeds

THE reawakening of interest in the developmental anatomy of the shoot apex has been paralleled by considerable advances in technique and by a growing realization that the answers to many genetical problems are locked up in a better understanding of the processes at work during the ontogeny of the organism. For a number of reasons, our knowledge of apical architecture is, so far, most advanced in the Gramineæ: here we are now in the happy position of realizing that much of the early controversy arose, not from incorrect recording of facts, but from the participants failing to realize that they were dealing with separate chapters of the same story. Although all members of the family probably conform with the scheme set out in the present résumé, for convenience reference is mainly made to species already discussed in the literature.

In the Gramineæ, the apex is always a comparatively elongated structure, with the cells at the extreme tip rather larger than those in the zone of leaf initiation and with less easily stained nuclei and a suggestion of being more vacuolated. The outer cells form a single thumb-shaped layer—the dermatogen—and normally only divide antichnally. They may sometimes originate from a single ill-defined apical 'initial', but more usually come from an even more indefinite group of 'initials'.

At the extreme tip it is often difficult to determine the arrangement of the internal cells, but a short distance back they are always found to be arranged in at least a hypodermis and sub-hypodermis, each one cell thick, which form concentric shells clothing a core of more vacuolated, less rapidly dividing tissue of a sort of 'apical pith'.

The dermatogen, hypodermis and sub-hypodermis maintain their individuality because the cells forming them divide only by antichnally walls until a new leaf is initiated. Then successive perichnally divisions occur in the cells of the dermatogen and hypodermis, while the cells of the sub-hypodermis under the insertion of the new primordium only divide perichnally once. On the other hand, at the origin of the axillary bud the sub-hypodermal cells repeatedly divide perichnally, but those of the dermatogen, and usually the hypodermis also, only divide antichnally.

The inner cells may originate in a variety of ways. In young seedlings and perhaps throughout most of the vegetative life of some slender grasses, they can all be traced back to a single 'segmenting' apical cell as in Fig. *a*. Sometimes (Fig. *b*) more than one apical cell is present, when the segments cut off produce the inner tissues as they are left behind. In both these types the first products of division of the one or more initials immediately divide once perichnally to give a cylinder (the hypodermis) one cell thick surrounding a core at first two cells in diameter. In older or more massive shoots there may be two superimposed initials (Fig. *c*), one giving rise to the hypodermis and the other to the rest of the internal tissue. Occasionally the situation in Fig. *d* occurs, where the inner initial cuts off cells to one side only, and these immediately divide once (the

outer cell giving the hypodermis of that side), while the upper initial cuts off cells destined on one side to be the hypodermis but on the other side to divide perichnally once, the outer cell becoming a hypodermal cell. These four types are those reputed to be usual for *Avena*¹, *Secale*² and *Triticum*² during their vegetative period, although even here a perichnally division in the 'initial' cell of the hypodermis every now and then leads to the displacement backwards of the old inner initial and its subsequent loss by differentiation (Fig. *e*). In other grasses, at least, apices can be found where there is a single 'initial' for the hypodermis and two or more for the central tissues (Fig. *f*). Here again an occasional perichnally division in the hypodermal initial leads to the displacement of the inner initial as in Figs. *g*, *h* and *i*. Fig. *h* also suggests a possible method of origin of apices of the more complex type seen in Fig. *j*, where there are two or more 'initials' for the hypodermis overlying a single one below. Similarly, Fig. *i* suggests a mode of origin of the more massive type of apex shown in Fig. *k* with two or more hypodermal initials and two or more initials below.

Progressively during ontogeny the apex usually tends to possess more initials, and the hypodermis tends to have an initial or initial group of its own superimposed upon the initial or initial groups of the more central cells. Although in the more massive types the hypodermis undoubtedly behaves as a distinct self-perpetuating layer for considerable periods, occasional perichnally divisions at the extreme tip may probably occur at any time and so lead to the displacement of the initials below. Not all species have apices of the same complexity at comparable times in their developmental history leading to inflorescence production. Thus, for example, although *Avena*¹, *Secale*² and *Triticum*² may have a separate initial or initial group for the hypodermis towards the end of the vegetative period, this only becomes a permanent feature from the time of inflorescence initiation, while in *Agropyron repens* Beauv. (un-

published) even the rhizome apex seems to have a discrete hypodermis and the aerial shoot often approximates to the state of affairs in Fig *k*. The condition represented in Fig *l* can be found at the tip of the developing inflorescence of *Agropyron*, but this may not be a permanent feature. The possibility of three tiers of internal initials is also suggested for some of the main shoots in bamboos (*Phyllostachys*³ and *Snocalamus*⁴), but there is need for further investigation here.

Axillary buds have a construction either similar to or simpler than the main apex. Thus in *Avena*, *Secale* and *Triticum*, where periclinal divisions are frequent in the hypodermis at the tip of the main shoot, a similar situation is found in the apices of the axillary buds. On the other hand, in *Agropyron*, *Snocalamus*⁴ and *Zea*, where the hypodermis remains as a discrete layer at the tip of the main shoot, periclinal divisions are absent from the apices of the axillary buds.

For want of a better term, the cells to which the internal layers can be traced back in the apex have been termed 'initials', but it is only rarely that they approach anything at all like the classical idea of an apical initial. They are not large, well-defined, well-vacuolated cells cutting off segments with a volume considerably smaller than their own. Instead they are usually rich in cytoplasm and divide into almost (? quite) equal parts, and the one which happens to be nearer the tip is destined to continue as the initial merely because of its position. All the cells of quite a large group are totipotent, and their positioning in the apex is probably governed by laws comparable with those which determine the packing patterns of bubbles in the end of a test tube rather than by any qualities inherent in the cells themselves. Moreover, the position taken up by a cell governs its subsequent development.

The view that the exact mode of origin of the inner tissues of the apex is not significant is further confirmed by the constant development behind the apex of the hypodermis and sub-hypodermis, often quite irrespective of details of segmentation at the actual tip, demonstrated especially by apices of the type shown in Fig *d*. From recent studies it is becoming increasingly evident that the zonation of all apices is to be thought of in terms of levels of relative differences in aeration, nutrition, etc. It is not a morphological but a metabolic zonation rather akin to a gardener's 'top-soil' and 'sub-soil'. The nearer a cell is to the surface, the more it tends to divide exclusively by antichlinal walls, an effect which bears absolutely no relationship to the number or positioning of the 'initial' cells, and which leads to the production a little way back from the extreme tip of clearly distinguishable layers, the numbers of which will tend to be greater the more massive the apex. In grass apices of the long type this zonation will be very noticeable, but it will be masked in short apices by the divisions connected with the onset of leaf and bud initiation. The metabolic view also makes the observed occasional periclinal divisions unconnected with leaf initiation in the dermatogen itself to be expected, especially in very young axillary buds or the plumules of young seedlings.

Since the exact origin and fate of the various layers are so flexible in the grass apex, Hanstein's terminology cannot be used in its strict sense, nor is the *tunica-carpus* terminology in Buder's⁵ (but not in Schmidt's⁶ and Foster's⁷) sense very useful. However, using these and Koch's⁸ similar terminology

(originally suggested for Gymnosperms) purely as descriptive of the tissue zonation of the apex without any implications as to derivation or destiny, the equivalents are as follows.

Tissue	Hanstein	Koch	<i>Tunica-carpus</i>
Outer layer	Dermatogen	Mantle (Hüllgewebe)	Tunica
Hypodermis	Outer periblem	Mantle	Tunica
Sub-hypodermis	Inner periblem	Mantle	Corpus (? or transition layer)
Inner core cells	Plerome	Central tissue	Corpus

The construction of the apex has considerable interest for the plant-breeder who wishes to obtain viable gametes by doubling the chromosome complement with colchicine, etc. This is obviously best achieved by affecting the tissues eventually traceable to the hypodermis of the flower-bud primordia. He need not consider whether the main axis has a single initial or a group of initials for both the hypodermis and the inner tissues, and whether or not periclinal divisions occur in the apical cells of the hypodermis of axillary buds. He must merely realize that the earlier he treats his seedling the better because (1) in young seedlings the whole of the hypodermis is being derived from fewer initials, so that should he have the good fortune to produce a doubling in an initial, it will produce a wide sector of cells with the new constitution, and it may also be the parent of some of the other initials when the group increases in number, (2) even if he succeeds in only doubling the complement of a hypodermal cell on the flank of the apex, if effected early this will be represented in all the tiller buds from that sector, whereas successively later local doubling in the hypodermis will only affect blocks of primary, secondary and then tertiary, etc., inflorescence buds (in the case of a paniculate inflorescence), or spikelet buds and later only floret initials.

EXPERIMENTAL MORPHOLOGY OF PTERIDOPHYTES

PHYSIOLOGICAL and experimental observations have hitherto played virtually no part in helping to elucidate problems connected with the organization of the plant body in Pteridophytes. The approach towards these problems has been almost exclusively morphological in inception and outlook. Some experimental investigations recently recorded by Prof C. W. Wardlaw (*Ann Bot*, New Series, 7, Nos 26 and 28, 8, Nos 30/31 and 32, April and Oct 1943 and April-July and Oct 1944) dealing with bud development and stelar morphology in ferns have yielded results of great interest and significance which indicate the value and potentialities of this previously neglected approach to morphological problems.

It has long been held that one of the morphological characteristics distinguishing ferns from seed

plants is the inconstancy in the positional relationship of buds to shoot and leaf in the former group. Though sometimes they occupy definite axillary positions, they commonly arise in extra-axillary positions which apparently show no fixed relationship to the foliar organs. Prof Wardlaw's observations, however, suggest that, though the final position of the bud is so variable, its point of initiation does in fact show a definite relation to the foliar organs, and the ultimate position it comes to occupy is explicable in terms of relative growth activities.

Investigations on *Matteuccia struthiopteris* and *Onoclea sensibilis* have shown that, on the normally unbranched rhizomes of these dictyostelic species, buds may be induced by removal of the terminal meristem. These buds are initiated in superficial areas of meristematic cells which, in the normal rhizome, remain quiescent. The origin of the patches of meristematic cells can be traced to the apical meristem, from which they become detached and persist on the surface of the shoot in definite positions corresponding to the point of union of the meristemes at the distal end of the leaf gap, that is, in the axis of a leaf but some distance above its insertion.

In *Dryopteris Filix-mas*, defoliation experiments involving the removal of fronds and destruction by puncturing with a needle of the smallest visible leaf primordia proved effective in bud formation. The buds were situated either on the leaf-base near its point of confluence with the shoot or some distance along the petiole. Investigation showed that the buds always arise on the shoot in an approximately axillary position, despite the abaxial position at some distance above the petiole base which they eventually may come to occupy. Their origin was traced to the activity of epidermal cells lying in close proximity to points of meristeme conjunction in the vascular meshwork of the shoot and therefore comparable in position with those of the other species investigated.

The position which the bud ultimately comes to occupy on the petiole is due to the very great transverse growth expansion of the basal region of a developing leaf primordium. This causes displacement of the much more slowly growing bud from its original axillary position, and leads to its being carried up on the enlarging base of a developing frond. The enlarging frond base on which the bud is thus caught up may lie in a longitudinal or a lateral position with respect to the bud, so that the bud may become separated in space from the leaf to which it originally stood in an axillary relationship.

Further observations along these lines may well reveal that the point of origin of buds is fundamentally the same in all ferns, and that the varied positions which they eventually occupy may be wholly explicable in terms of specific growth distribution in shoot and leaf.

In the field of stelar morphology, chief consideration has always been devoted to fully differentiated tissue systems, and though a fairly complete picture has been obtained of the progressive increase in complexity of the stele during ontogeny, little attention has been paid to the development of the shoot as a whole from the apex backwards. Hence developmental studies in the stelar morphology of ferns, comparable in detail with the ontogenetic studies of their reproductive structures or with the dynamic aspect of tissue differentiation behind the growing point in the Angiosperms, are not available.

Prof Wardlaw recognizes two phases in the development of vascular tissues, namely, the "initial differentiation", whereby vascular tissue can be distinguished from cortical tissue, and the "subsequent differentiation" characterized by the specialized development of the constituent vascular elements. It is in the region situated immediately below the apical meristem that the "initial differentiation" takes place, and it is suggested as a working hypothesis that this initial differentiation of vascular tissue is inseparably connected with the immediate proximity of an apical meristem in a state of active growth, its position and behaviour being causally related to one or more unspecified substances diffusing from the meristematic cells.

Evidence adduced for the Pteridophytes in general is fully in accord with the fact that wherever an actively growing apex is present, vascular tissue may be observed in the process of differentiation immediately behind it. Moreover, that the maintenance of the actively meristematic condition is all-important is indicated by the disappearance of the zone of initial differentiation behind dormant apices. It is shown that the discontinuous vascular strands which have been described by Holloway in large prothall of *Psilotum triquetrum* are associated with discontinuous apical activity, while instances cited of vascular tissue differentiation in experimentally induced buds on fern rhizomes, in the protocorms of Lycopods and their attached leaves, and in certain regenerative growth processes which have been described in *Lycopodium Selago*, all clearly point to the fact that where the apical growth is not actively maintained, stelar tissue is not differentiated.

The application of experimental methods to the problem of the relation of leaf development to stelar morphology in ferns has yielded results of outstanding interest. These results throw new light on the factors determining the form of the axial stele and supply an answer to the much-debated question of the cauline versus foliar nature of the stelar stele.

It was observed that in *Dryopteris Filix-mas* immediately below the apical meristem, there is an uninterrupted ring of vascular tissue in the initial stage of differentiation, while in the earliest stage of development of the fronds the vascular supply to the young primordia shows no leaf gaps. These develop a little later, their formation being associated with mechanical stresses resulting from the enlargement of the vascular systems of the leaf bases. Experimental verification of this relationship was sought by defoliating rhizomes and destroying the young leaf primordia by needle puncturing with a micro-manipulator. The apical meristematic cone alone was left intact. The rhizomes were planted in moist peat and new leaf primordia were regularly destroyed as they developed. The suppression of leaf growth was found to lead to the failure of leaf gaps to form, and therefore to the substitution of a solenostele in place of the dictyostele characteristic of this species. When new leaf primordia were allowed to develop again on treated rhizomes, the specimens showed solenostely in the treated region of the shoot, with a return to normal dictyostely in the terminal region. Similar experimentally induced solenosteles were obtained in *Onoclea sensibilis*. The development of a substantial shoot stele in both species in the absence of any associated leaf growth affords proof of the truly cauline nature of the stele.

W. A. SLEDGE

ORGANIZATION OF RESEARCH IN THE U.S.S.R. INSTITUTE OF PHYSICAL PROBLEMS

ON May 18, 1943, Prof P Kapitza presented a very long report at the meeting of the presidium of the U S S R Academy of Sciences in which he dealt with the organization of scientific work at the Academy of Sciences. An official translation into English of parts of the report has recently been made available in Great Britain in Bulletin, 9-10, 1943, of *WORKS*, the organ of the U S S R Society for Cultural Relations with Foreign Countries and has been used in the preparation of the following account*.

On the basis of his experience at Cambridge, Prof Kapitza felt that the organizational forms of scientific work accepted in the West could not be applied unchanged in the U S S R. "This is principally caused by the fact that in our socialist country science occupies a special place. Of course it is well known and commonly accepted in the other countries too, that science plays a great role in the development of the culture and technology of the country. But in our country science is recognized as one of the essential mainstays of the development of culture and is accorded a leading position in the development of our technology and national economy. For this reason the organization of science in our country must have a more purposeful character than that to be found in other countries, where it is rather accidental and spontaneous. The connection between science and life must be close and more complete."

As Prof Kapitza's Institute is so young—it is only even or eight years old—and moreover is devoted to work on strong magnetic fields and low temperatures, which was but little developed in the U S S R. At the time, the first years were spent in forming and training the scientific personnel and staff. "The question I put before myself from the very outset was what sort of problems must an institute of the Academy of Sciences work up? I had in mind an institute of physics or an institute devoted to research in the field of natural science. I emphasize further that I am speaking in particular of the organization of an institute of the Academy of Sciences. What is the Academy of Sciences? It is the Chief Headquarters of Soviet Science. In my opinion it is called upon to direct all our science ideologically, from top to bottom, along a sound channel. Each of its separate institutes must pursue the same policy, that is, aspire to wield a directing influence on science in the field in which it is working, and strive to bring it into the front ranks. For this reason, the first task which an institute of the Academy of Sciences must set itself is to study a 'great science.' In the official translation, 'great' is used throughout, but from the definition given it would appear that the correct translation is 'pure' as distinct from applied science. 'Great' science is 'the science that studies the essential phenomena necessary for the most profound knowledge of nature', but it is explained that "the task of a science is to give the necessary knowledge for transforming nature so that it can serve man in his cultural development." For this reason the choice of the fields of research of an institution is extra-

ordinarily important, and Prof Kapitza would choose the fields of low temperatures, the atomic nucleus and the solid state as the most important at the present time.

"Only a person with a profound creative talent and one who treats his work creatively can achieve considerable success in 'great science'. For this reason the leading group of the institute must undoubtedly be formed from a few carefully picked workers who must devote themselves wholeheartedly to scientific work with not more than twenty per cent of their time given up to social or other non-scientific activities." From the emphasis laid upon conditions that the worker must be able to stay in the laboratory and himself work there, it is clear that Prof Kapitza would not approve of what might be called 'office' research in which meetings and memoranda continually interrupt actual research work. "Only when one works in the laboratory oneself, with one's own hands, conducting experiments even the most routine parts of them,—only under these conditions can real results be achieved in science. Good work cannot be done with other people's hands. I am certain, that the very moment even the greatest scientist stops working in the laboratory himself, he not only ceases to develop but, in general, ceases to be a scientist. These principles are very important, but they belong only to peace-time, war-time forces us to act differently."

The greatest emphasis is laid upon these principles, particularly with beginners. "For this purpose I try to put their work into rather rigid organizational frames. For instance, a scientific worker must not be occupied with several subjects at one time, especially if he is at the beginning of his scientific career. When the scientific worker has grown somewhat and become more experienced, he may be able to work simultaneously on two or three subjects as a rare exception, but he must always begin with one."

Attention is then directed to the dangers of overwork. "The next point in the organization to ensure successful work, is that the scientist must work in the laboratory a limited number of hours. Long spells of work are harmful, it is exhausting and lowers a person's creative powers." The regime observed by the workers in the Institute for Physical Problems at Moscow is that usually all laboratory work stops at 6 p.m., after which the worker leaves for home "to ponder on his work, read, study and rest." Exceptionally, by permission of the vice-director, work may continue until 8 p.m. Night work is sanctioned only by the director when it is justified by technical necessities of the experiment.

The next problems discussed are how such an Institute can influence the development of the science of the country and can avoid becoming a closed and isolated unit, which latter would be contrary to one of the principles laid down earlier. Several means are discussed. First of all, full advantage must be taken of the privileges of an institute of the Academy of Sciences, whereby the Institute has access to "rich and modern technical equipment" and to a wide field in selecting experienced staff. The special plant for making liquid helium in quantity gives the Institute for Physical Problems exceptional possibilities for doing experiments at very low temperatures. Next, these facilities are made available to workers in other institutes. Such visits are usually arranged as follows: "The comrade who wishes to work at our institute is invited to our scientific meeting where he reports on

* A complete translation of the speech together with that of a long discussion has been made by the Science Section of the Society for Cultural Relations with the U S S R, 98 Gower Street, London, W C 1.

the experiment he proposes to conduct. This is discussed and, if the proposal is of scientifically grounded interest and the author is sufficiently qualified, he is given the opportunity to do his work." Not more than two or three outside workers can be accommodated at the same time without disorganizing the main work of the Institute. So far there have been more suitable applications than could be accommodated.

These guests form a vital link with other institutes, for not only is a knowledge of the work of the Institute for Physical Problems spread by them but also the guests keep the Institute informed of what is being done elsewhere. Prof Kapitza is no believer in isolation, as the following passage shows: "In the future similar vital contacts must be established with scientists in other countries. Scientific workers from abroad visited us during the first years of the existence of our Institute. But in recent years the political situation has grown so complicated, that though there were those who wanted to come here, our connections with foreign countries had been severed, so we can only speak of this aspect of our relations with foreign scientists in view of plans for the future. But these relations must, of course, be deemed a normal and sound condition of the work of any academic institute, because science throughout the world comprises one indivisible whole."

Another function of the Institute is to train scientific workers. Prof Kapitza was not satisfied with the external method of selecting postgraduate students. "Only the institute itself can train its future personnel, and it must do so with great diligence, by gradually nurturing them from youth." The method of selection used for two or three years before the War gave unique opportunities to students at the University of Moscow. "Taking advantage of the fact that we possess greater amounts of liquid helium for experiments at low temperatures than the refrigerating laboratories of the whole world put together, we were in a position to set up a practicum at the institute, which is attended by every student of the Moscow University School of Physics." At first, only the best students were admitted, but later every student was allowed to do two or three experiments, using liquid helium for the study of such phenomena as superconductivity and magnetic properties near 0°A . The best of the students, if they wished, were allowed to do more than the three experiments, and from the beginning of their third or fourth university year were in close contact with the Institute. Later they were invited to help with the research work as junior laboratory assistants. Prof Kapitza thinks that if the scheme had not been interrupted by war, probably one out of ten or fifteen of these students, on completing their graduate work, would have proved sufficiently talented to remain on the main scientific staff of the Institute.

"This method of observing young students from the time they are at the university, the thorough and constant verification of their abilities is, in my opinion, the only correct way of selecting young scientific workers, so far. As you grow older, it is only young people, only your pupils, who can save you from premature mental staleness. Of course, every pupil must know more about the field in which he is working than his teacher. And who teaches the teacher, but his pupils? Thanks to his experience the teacher supervises the general fund of the work, but he is taught by his pupils, who deepen his knowledge and extend his scope." The difficulty of making

correct statements about the human being doing creative work is illustrated by Kapitza's statement that "without pupils the scientist very soon dies as a creative unit and ceases to advance." Faraday had no pupils. Rutherford told Kapitza that "it is only because of my pupils that I, too, feel so young." Prof Kapitza ends the first section of his address with the words "as I myself am approaching old age, I feel that intercourse with youth must be the *modus vivendi*, safeguarding one from withering away and insuring the maintenance of courage and interest in all that is new and advanced in science. Conservatism in science is worse than premature death to a scientist, it acts as a brake on the development of science."

W. H. GEORGE

OBITUARIES

Dr G. D. Bengough, F.R.S.

DR GUY DUNSTAN BENGOUGH, whose name is particularly associated with research on the corrosion of metals, died in the East Sussex Hospital, St Leonards, on January 20. He was born in 1876, the son of Major E. B. Bengough, and was educated at Malvern and at Selwyn College, Cambridge. He then studied metallurgy at the Royal School of Mines and worked for a short time at the Royal Mint, gaining experience in research under Sir William Roberts-Austen. He went to Burma for practical experience in the extraction of gold and tin ores, and then held teaching posts in the Universities of Birmingham and Liverpool.

While at Liverpool, Bengough published papers on the rupture of metals at high temperatures, in which he showed that the normal fracture through the crystals of a metal gave place to one passing between the crystal grains when a certain critical temperature was exceeded. This he attributed to the presence between the grains of a non-crystalline layer, having some of the properties of a glass, being rigid at low and viscous at high temperatures. The same idea was suggested independently by Dr Rosenham, and this conception of an 'amorphous intercrystalline cement', although questioned by some, became popular, and long served as a basis for research.

It was while at Liverpool that Bengough began work on the corrosion of metals, especially brass marine condenser tubes, for the Institute of Metals. A series of reports was issued, in which the conditions determining general corrosion and pitting were examined, and new experimental methods were devised. The work was interrupted by the War of 1914-18. Bengough obtained a commission in the Royal Artillery, and in 1916 was captain and adjutant. He was, however, seconded for work for the Admiralty and later for the Royal Flying Corps, and continued work on corrosion in the Royal School of Mines. He later became a principal scientific officer in the Chemical Research Laboratory at Teddington, and from then onwards devoted himself to the investigation of corrosion, giving special attention to the design of apparatus.

In 1926 Bengough devised the method of anodic protection of aluminium and its alloys which proved of very great industrial value. Not only did the film produced by his method give a high degree of resistance to corrosion, but also it could be given a definite degree of porosity, so that the surface could be made to take dyes or pigments, opening up a wide field of

decorative work. He was also responsible for a method of protecting magnesium and its alloys by depositing selenium, which, however, had certain practical disadvantages.

Much of Bengough's later work was done for the Joint Corrosion Committee of the Iron and Steel Industrial Research Council and the Iron and Steel Institute, and after retiring from Teddington in 1936, he continued to act as consultant to that body and to the Department of Scientific and Industrial Research, being chairman of the Marine Corrosion Sub-Committee.

Bengough's work was marked by a high standard of accuracy. He devised methods by which extraneous factors were so far as possible excluded, so that the results were reproducible. By using carefully designed apparatus, he determined the course of the corrosion process by measuring the absorption of oxygen and when necessary the evolution of hydrogen, so that characteristic corrosion-time curves could be drawn. Such carefully selected conditions cannot, of course, reproduce those of attack on a ship's plate or a condenser tube, and the relations between laboratory results and practical experience have been the subject of much controversy. Bengough laid most stress on the properties of the products of corrosion in determining its subsequent course, whereas Dr U R Evans and his collaborators attached chief importance to the principle of differential aeration. The two investigators were approaching the problem from different angles, and their views were less irreconcilable than they had seemed at first, so that in 1938 a joint statement was issued which showed how great was the measure of agreement. A series of six papers by Bengough and his colleagues in the *Proceedings of the Royal Society*, of which he was elected a fellow in 1938, contains an account of a long series of quantitative experiments on corrosion. Other laboratory work is described in the reports of the Corrosion Committee published by the Iron and Steel Institute, and here his chief service was that of laying down the conditions which must be observed in making standard tests of corrodibility.

Tall and military in appearance and seemingly robust, Bengough had long periods of serious illness before that which led to his death. He was a good chairman and always showed good temper and courtesy in dealing with a notoriously controversial subject.

Dr. Bengough married Constance Helen, daughter of Lieut-Colonel Jelf-Sharp, who survives him.

C H DESCH

Prof. V. I. Vernadsky

PROF VLADIMIR IVANOVICH VERNADSKY, one of the leading mineralogists and geochemists in the U.S.S.R., died on January 6. He was born at St Petersburg on March 12 (February 28, Old Style), 1863. After graduating at the University of St Petersburg in 1886, he spent some time in Paris working in the laboratories of Le Chatelier and Curie, and in 1896 was appointed professor of mineralogy at the University of Moscow. In 1906 he was elected a member of the Russian Academy of Sciences.

Prof Vernadsky's early work was devoted to a chemical study of aluminosilicates, a subject which he later expanded and applied in a wider field of the structure of silicates and especially of kaolinite, feldspars and chlorites. At the same time he was

working on descriptive mineralogy and he described and named a number of new minerals. In his lectures at the University he began to break new ground by stressing the genetic aspect in mineralogy. This genetic approach to mineralogy was fully developed in his books "Essay on Descriptive Mineralogy" (1908, 1910) and "History of Minerals of the Earth's Crust" (1925, 1933). Eventually genetic mineralogy overstepped its proper boundaries and became merged in the far wider field of geochemistry. Thus Vernadsky may be considered the founder of the new Russian school of geochemistry, which has made such gigantic strides during the last three decades.

The greater part of Vernadsky's work on geochemistry appeared in the form of numerous papers, but a good presentation of it may be found in his book "La géochimie", published in French in 1924. It is a most stimulating book, full of daring ideas and wide generalizations. But even more daring is his book "La biosphère", published in 1929, in which he made an attempt to incorporate biological processes into his general scheme of geochemistry.

Endowed with a versatile genius and full of tremendous energy and enthusiasm, Vernadsky spread his activities far and wide. He organized regular research in mineralogy and geochemistry, helped to establish the Mineralogical Museum in Moscow, promoted the establishment of numerous scientific institutions—such as the Biogeochemical Laboratory, the Radium Institute, a permanent committee for the study of meteorites, and others. He was also the founder and the first president of the Ukrainian Academy of Sciences. Vernadsky was well known outside the U.S.S.R. Since 1920 he spent some years in Paris and Prague working and lecturing. He was a member of the Paris Academy of Sciences and the Czechoslovak Academy. He visited Great Britain in 1923, when he took part in the meeting of the British Association in Liverpool.

Vernadsky's direct contributions to science are considerable, but they are dwarfed by the greater importance of his influence on the development of new ideas in geochemistry and mineralogy. As a teacher he was most stimulating. He could easily divert the wealth of his erudition into fresh channels and mark out new lines of research. He was greatly admired and loved by his pupils and colleagues, even by those who violently opposed his views.

A bibliography of Vernadsky's works up to 1936 was given in the 'Vernadsky Jubilee Volume' published by the Academy of Sciences of the U.S.S.R., two articles in *Bull. Acad. Sci. URSS, Géol. Sér.*, No. 1 (1944), one by D P Grigoryev (p. 25) and the other by V G Kryzhanovsky (p. 35) give an account of his work, and a short account of the development of geochemistry in the U.S.S.R. has appeared in *Nature* (154, 814, 1944). S I TOMKEIEFF

WE regret to announce the following deaths:

LORD DAWSON OF PENN, PC, GCVO, KCB, president during 1931–38 of the Royal College of Physicians, on March 7, aged seventy-nine.

Prof F W Eurich, emeritus professor of forensic medicine in the University of Leeds, known for his work on anthrax, on February 16, aged seventy-seven.

Sir Duncan Wilson, CVO, CBE, until 1940 chief inspector of factories (Home Office), and secretary during 1918–30 of the Industrial Health Research Board, on March 1, aged sixty-nine.

NEWS and VIEWS

Royal Scottish Museum, Edinburgh

Mr Thomas Rowatt, OBE

ON reaching the age limit, Mr Thomas Rowatt has recently retired from the directorship of the Royal Scottish Museum, which he has held since 1934. He entered the Civil Service as assistant in the Technological Department of the Royal Scottish Museum in 1902, became assistant-keeper in 1909 and keeper of the Department in 1921. The period of his directorship marked steady progress in the development of the activities of the Museum, and though the building was closed to the public on the outbreak of the War, and its valuable collections were dispersed to places of safety, Mr Rowatt has in recent years arranged for special exhibits which have proved attractive to the people of Edinburgh and to the city's many visitors from overseas. Perhaps the most popular of these has been the present Fisheries Exhibition, arranged in co-operation with the Fisheries Department of the Scottish Home Office, at which the comprehensive collection of exhibits illustrating many aspects of Scottish fisheries has been supplemented by weekly lectures on a wide variety of fishery topics by recognized experts.

Dr. Douglas A. Allan

MR ROWATT has been succeeded in the directorship by Dr Douglas A. Allan, formerly director of the Liverpool Public Museums. Dr Allan is a graduate of the University of Edinburgh, where he specialized in geology, taking part in the late Dr W. S. Bruce's expeditions to Spitsbergen, and acting as assistant in the University Department of Geology under the late Prof. T. J. Jehu. During 1925-29 he was lecturer in geology in Armstrong College, University of Durham, and in the latter year was appointed director of the Liverpool Museums. Dr Allan has taken an active part in the promotion of museum interests as chairman of the Museums Association and as a member of the Post-War Reconstruction Committee on Museums and Art Galleries. Last year he was awarded the Neill Gold Medal of the Royal Society of Edinburgh for his researches on the geology of the Highland border in Angus and Perthshire.

Biologist to North of Scotland Hydro-Electric Board

AN appointment of more than usual interest to naturalists has been announced by the North of Scotland Hydro-Electric Board, the authority for the development of water-power schemes over a considerable area of the most attractive scenery in Scotland. In 1943 the Board appointed Mr W. L. Calderwood, formerly inspector of Scottish salmon fisheries, as its principal consulting adviser on fishery matters, and will continue in that capacity, but a full-time fishery adviser and biologist, Dr John Berry, has now been appointed to ensure that in the planning of new schemes due attention will be given to all aspects which affect wild life. Dr Berry's wide interests in natural history fit him well for such a post. For some time he was director of the Freshwater Fisheries Research Station at University College, Southampton, and before the War he carried out salmon research for the Fishery Board for Scotland and the Moray Firth Salmon Fishery Company. In 1939 he published for the International Wildfowl

Inquiry an exhaustive volume on "The Status and Distribution of Wild Geese and Wild Duck in Scotland". During the War he has been officer-in-charge of Press censorship in Scotland, but naturalists will welcome his return to his proper vocation.

Royal Society of Edinburgh

Awards

THE Council of the Royal Society of Edinburgh has awarded the Gunning Victoria Jubilee Prize, for the period 1940-44, to Prof. H. W. Turnbull, University of St. Andrews, for his distinguished contributions to mathematical science and the history of mathematics, and the Makdougall-Brisbane Prize, for the period 1942-44, jointly to Prof. Max Born and Dr. H. W. Peng, University of Edinburgh, for their papers on "Quantum Mechanics of Fields" published in the *Proceedings* of the Society within the period of the award.

New Fellows

THE following have been elected ordinary fellows of the Royal Society of Edinburgh: Dr Robert Aitken, lecturer in dermatology, University of Edinburgh; Prof. C. H. Browning, professor of bacteriology, University of Glasgow; Mr A. M. Bryan, mining engineer; Dr William Burns, agricultural commissioner with the Government of India (retired); Dr L. B. C. Cunningham, superintendent of the Air Warfare Analysis Section, Ministry of Aircraft Production; Prof. A. Durward, professor of anatomy, University of Leeds; Dr A. Erdélyi, lecturer in the Department of Mathematics, University of Edinburgh; Dr A. Ghaffar, lecturer in physiology, Robertson Medical School, Nagpur; Dr W. Spence Haldane, teacher of chemistry, Dunfermline High School; Mr E. H. E. Havelock, secretary of the Development Commission; Dr R. E. Illingworth, lecturer on chemistry, School of Medicine, Royal Colleges; Dr John Jardine, principal assistant secretary, Scottish Education Department; Dr D. D. Logan, medical practitioner, Woodside, Lanarkshire; Mr I. S. Macadam, secretary of the Royal Institute of International Affairs; Dr D. M. McIntosh, director of education for the County of Fife; Mr H. P. Morrison, publisher; Prof. J. T. Randall, professor of natural philosophy, University of St. Andrews; Dr James Stirling, lecturer in plant physiology, University of Liverpool; Mr Merion Thomas, reader in plant physiology, King's College, University of Durham; Dr Robert Walmsley, senior lecturer in anatomy, University of Edinburgh; Prof. S. J. Watson, Department of Agriculture, University of Edinburgh, and principal, Edinburgh and East of Scotland College of Agriculture; Mr James Wilkie, secretary of the Carnegie United Kingdom Trust; Mr D. C. Wilson, director of T. and H. Smith, Ltd., Corstorphine; Dr N. C. Wright, director of the Hannah Dairy Research Institute, Ayr; Prof. C. M. Yonge, regius professor of zoology, University of Glasgow.

New Aeronautical Research Establishment

SIR STAFFORD CRIPPS, Minister of Aircraft Production, in reply to a question in Parliament, has stated that it is proposed to build a new research and development centre for both civil and military aircraft construction at Bedford. Many new problems have now to be faced with the approach of supersonic speeds, which will need much special apparatus and

up-to-date wind tunnels. It is intended to make a beginning as soon as possible, but the rate at which the equipment will be provided will naturally depend upon the finance available to meet what will inevitably be a costly project. The transfer of both apparatus and staff from the present Royal Aircraft Establishment at Farnborough will be gradual. Farnborough will eventually be retained for special research and development on armament, instruments and such auxiliary services. It is understood that the new centre will not affect the R A F station at Cardington, but will be an extension of a present American bomber station and the Bedford airport at Thurlleigh.

The adoption of this scheme completes plans that have been under discussion for a long time in the aeronautical world, and is perhaps the widest organization of industrial applied science ever attempted in Great Britain. The experimentation relative to the immediate progress in aircraft design and the solving of problems arising upon aircraft in use will be the province of the designing and constructing firms. At the Royal Aircraft Establishment the Air Ministry, as purchasers and users of aircraft for the Fighting Forces and possibly to a certain extent for air transport, will deal with their special problems, many of which must be handled in this way as necessarily they will be secret. The new organization will deal with long-range fundamental research of a general nature, that will add to the knowledge of all who use the science of aeronautics in any way. This should extend the usefulness of the Aeronautical Research Committee, a body which, acting in an advisory capacity, has been largely dependent upon the goodwill and the capacity of the industry, Government establishments, and the universities, for the carrying out of its suggestions. The importance of this is obvious, and it is hoped that its development will be able to proceed at a reasonably rapid rate.

Royal Commission for the Exhibition of 1851

At the 148th meeting of the Commissioners of the Exhibition of 1851, held on May 6, the Princess Royal was elected president of the Royal Commission in succession to the late Duke of Kent. In his survey of the work of the Board of Management during the period immediately before and after the outbreak of war, Lord Macmillan gave reasons for the partial suspension of the scholarship schemes in 1939, when no fresh awards were made although existing scholarships were continued until their holders were absorbed in the national war effort. So great was the demand for the Commission's experienced research workers and engineering students that by the end of 1940 practically all these men and women had relinquished their awards to take up appointments in the technical branches of the services or in special work for the war industries. Referring to the scientific research awards of the Commission, Lord Macmillan emphasized that the scholarship scheme has produced many of the most eminent men of science in academic, industrial and professional life, including sixty-six fellows of the Royal Society and no less than six Nobel laureates. The Commission's industrial bursary scheme has also been very successful and has helped to place in industry more than six hundred graduates who could not depend on their parents for financial support after their university scholarships came to an end. Sir Robert Robinson described the work of

the Science Scholarships Committee. Since 1921 when the earlier scheme was revised, 90 senior students and 149 overseas scholars from the Dominions have been appointed. The value of the material derived from the Dominions has been more than gratifying. Their records as a whole show that they are using the knowledge and experience gained as scholars to very great advantage in the scientific service of the Commonwealth.

Coasts of England and Wales

A SURVEY of the scenic qualities of the coasts of England and Wales has been made by Mr J. Steers at the instance of the Ministry of Town and Country Planning. The results are embodied in a map accompanying a paper in the *Geographical Journal* of July-August 1944. The greater part of the coastal scenery is classified as of good or very good quality, with exceptional quality mainly in parts of Wales and Cornwall. Comparatively little outside certain industrial areas, has been ruined, but Mr Steers notes the frequent occurrence of bad scattered development marked by huts and bungalows on parts of the East Anglian coast and elsewhere, including, no doubt, coasts in the south-east, an area for the time excluded from the survey. Only a few stretches of coast-line up to the present are under the National Trust, and it is evident that steps will need to be taken speedily not only to check undesirable building, but also to ensure access to the coast-line. Nor must the coast-line be considered in any rigid conception. In many parts it is a zone, and not a coast, that must be protected. Mr Steers argues that the main problems relating to the maintenance of our coast-line from both a scenic and also a physical point of view should be the work of a national organization.

Individual Welfare and Human Progress

THE R A F Penrose Memorial Lecture delivered by the Right Hon. H. B. Butler, British Minister at Washington, has been published (*Proc. Am. Phil. Soc.*, 88, 151, 1944). Mr Butler discusses the lessons derived from the work of the International Labour Organisation during the last twenty-five years. Its organization, he says, has needed little amendment during its first twenty-five years. It was founded in the belief that the welfare of the common man must be one of the main objectives of human society, the supreme aim of which is individual progress. There can be no peace without social justice, nor can we have social justice without peace. War must go, but economic upheaval must also be prevented. The great slump of 1929-33, which was due, not to inability to produce, but to lack of purchasing power, is likely to recur after the present War, to a more serious degree. That slurred taught us that international economic unity is essential. Nations must act together to prevent repetition of it. Wise planning is not enough. There must be a true conception of life as well. The Fascist danger, spread far and wide, will still be a menace after the War, and it will be one of the tasks of the International Labour Organisation, which has been repudiated by all the Fascist States, to fight it. If we follow purely egoistic and materialistic aims and ignore the good of our neighbours, putting economic values above spiritual values, we shall inevitably decline. The cynicism of despair will be equally fatal. B.

we believe that humanity, by its own exertions, attain a higher and nobler destiny than any it has yet known, then we shall not fail.

Overhead Lines and Outdoor Equipment on A.C. Systems

IN a paper read recently in London before the Institution of Electrical Engineers, R C Hatton and McCombe lay down the guiding principles that for an efficient operation, maintenance and testing of electrical equipment in complex A.C. systems, it is of fundamental importance to provide adequate transport and communication systems, a carefully selected and trained staff at strategic points, and centralized control of all operations, and to enforce the strict observance of a suitable code of safety regulations and maintenance of the various components of overhead lines and outdoor sub-stations, which the authors' experience has shown to be necessary or desirable, is detailed, and suitable intervals for such maintenance work are indicated. An analysis of its use is made for both the overhead lines and transformers on the system, and the steps are described which have been taken, or which should be taken, counteracting them. The predominance of faults due to lightning is emphasized and the precautions which can be taken are discussed. Finally, the authors indicate the developments they consider to be desirable to minimize maintenance costs and at the same time to improve the reliability of electricity distribution, with special reference to the system of Yorkshire Electric Power Co.

Institution of Electrical Engineers Scholarships for 1945

THE Council of the Institution of Electrical Engineers will this year consider the award of three arch scholarships and grants, and seven scholarships for undergraduates and students to attend universities and technical colleges. These awards will be made subject to the regulations laid down by the Ministry of Labour and National Service regarding candidates' ages at the commencement of their courses. *Research Scholarships*: Ferranti Scholarship, £100 per annum for two years, Swan Memorial Scholarship, £120 for one year, War Thanksgiving Education and Research Fund, grants up to £100 one year. *Student Scholarships*: Duddell Scholarship, £150 per annum for three years, William die Esson Scholarship, £120 per annum for two years, renewable in approved cases for a third year, Angus Thompson Scholarship, £100 per annum, tuition fees for two years, David Hughes Scholarship, £100 for one year, Salomons Scholarship, £100 for one year, Paul Scholarship, £50 per annum for two years, Thorrowgood Scholarship, £100 per annum for two years. Full particulars can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, WC2. The closing date for receiving applications is April 15, 1945, and the awards will be made towards the end of June.

Conference on X-Ray Diffraction Analysis

THE X-ray Analysis Group of the Institute of Physics will hold a conference during April 12 and 13, at the Royal Institution, London, under the chairmanship of Sir Lawrence Bragg. The programme includes a lecture by Prof J D Bernal on "The Nature of X-ray Analysis", and a series of papers

on new and improved methods. Discussions are to be included on the equipment of a laboratory for X-ray analysis, the interpretation of X-ray diffraction by optical principles, and the proposal to convert X-ray wave-lengths to absolute values. Further particulars may be obtained from the honorary secretary of the Group, Dr H Lipson, Crystallographic Laboratory, Free School Lane, Cambridge.

Care of Laboratory Animals

THE Universities Federation for Animal Welfare (UFAW), 284 Regent's Park Road, Finchley, London, N 3, has been collecting information for a handbook on the care of laboratory animals. Major C W Hume and Dr F Jean Vinter state that they still require information about maintaining healthy stocks of the larger species—cats, dogs, the smaller ungulates and primates. These species will not be dealt with in detail in the handbook, but references will be given to published accounts of methods of maintaining healthy and contented stocks and a list provided of laboratories at which advice on the subject can be given at first-hand.

Announcements

THE Senatus of the University of Edinburgh has awarded Cameron Prizes for 1945 "for a highly important and valuable addition to Practical Therapeutics" to Sir Alexander Fleming in recognition of his discovery of penicillin, and to Sir Howard Florey in recognition of his work in making possible the clinical application of penicillin.

THE title of professor of chemical pathology in the University of London has been conferred on Dr E J King, in respect of the post held by him at the British Postgraduate Medical School.

PROF DOUGLAS HAY, honorary professor of mining in the University of Sheffield, has been appointed a member of the Board for Mining Examinations in succession to the late Mr Robert Clive.

THE trustees of the Miners' Welfare National Scholarship Scheme, established by the Miners' Welfare Commission for the provision of university scholarships for workers in or about coal mines and their sons and daughters, have appointed Prof J F Duff, vice-chancellor of the University of Durham, to be chairman of the Selection Committee in succession to Sir Franklin Sibly, and Prof W E Curtis, professor of physics at King's College, Newcastle-upon-Tyne, to be a member of the Committee in succession to Prof A M Tyndall.

THE Royal Society of South Africa elected the following to fellowship during 1944: Dr R A Dyer, chief of the Division of Botany and Plant Pathology, Pretoria, well known for work on the Euphorbias, Dr N Sapeika, assistant professor of pharmacology, University of Cape Town, and author of "Actions and Uses of Drugs", and L H Wells, lecturer in anatomy, University of the Witwatersrand, and anthropologist.

ERRATUM In *Nature* of February 24, p 233, Prof Sydney Chapman was wrongly described as "chief professor of mathematics, University of London". Prof Chapman is chief professor of mathematics in the Imperial College of Science and Technology, University of London.

A New Vitamin A

AN earlier publication¹ presented evidence which indicated that fish liver oils contain a substance (or substances) which has vitamin A activity but differs in properties from the vitamin A (here designated A₁) previously obtained in crystalline form.² Subsequent research has revealed that the newly recognized compound occurs in fish liver oils in substantial amounts, being responsible for approximately one third of their total vitamin A potency.

We have succeeded in isolating the vitamer* from fish liver oils in pure form. It crystallizes as light yellow needles (m.p. 59–60°) which contrast with the yellow prisms (m.p. 62–64°) of vitamin A₁. It has an absorption maximum at 328 mμ ($E_{1\text{ cm}}^{1\text{ per cent}} = 1675$) while vitamin A₁ has its absorption maximum at 325 mμ ($E_{1\text{ cm}}^{1\text{ per cent}} = 1750$). It is an alcohol which forms a red anthraquinone carboxylate (m.p. 130–131°), while vitamin A₁ yields a corresponding ester which is yellow (m.p. 123–124°). By treatment with alcoholic hydrochloric acid it forms the same anhydro compound (m.p. 76–77°)³ as vitamin A₁, but the reaction proceeds much more slowly. It is more stable to atmospheric oxidation than vitamin A₁.

The constitution of the new vitamer has not yet been definitely established. The available evidence, however, suggests that it may be a geometrical isomer of vitamin A₁ differing in the *cis-trans* configuration at the double bond nearest the hydroxyl group.

A method has been developed for estimating the percentage of the new substance in fish liver oils and concentrates. This is based on the observation that maleic anhydride reacts more slowly with it in benzene solution than with vitamin A₁. Analyses of samples of soupfin shark and dogfish liver oil showed that 30 per cent and 33 per cent, respectively, of the vitamin A was the newly recognized compound.

A second method of estimation of the vitamer depends on the fact that it forms the anhydro compound on treatment with alcoholic hydrochloric acid much more slowly than vitamin A₁. The procedure is less useful than the one just described because it must be carried out on the saponified fish liver oil or concentrate.

A preliminary bio-assay on the new compound has indicated that its potency is nearly the same in kind and magnitude as that of vitamin A₁. More extensive assays are in progress.

The recognition that the vitamin A activity of fish liver oils is due to at least two different substances emphasizes the need for an improved system of nomenclature. The term 'axerophthol' proposed by Karrer for vitamin A₁ has not gained general usage and moreover establishes no basis for naming newly discovered vitamers. The use of subscripts is also unsatisfactory. For example, while the vitamin A₂ found in the liver oils from freshwater fish possesses curative powers for the vitamin A-deficiency

syndrome, it probably has a basically different structural formula than vitamin A₁.

We have consulted various authorities in the United States and have suggested that the A-vitamins in fish liver oils be named from the genus fish in which they were first found or in which they occur in concentrated form. Suggested terms were 'gadol' for vitamin A₁ from *Gadus*, the cod, a 'galol' for the new vitamer from *Gahdæ*, the shark. If other A vitamins are discovered in the future they could be named readily by this system, which is now being considered by the Committee on Biochemical Nomenclature of the U.S. National Research Council.

Antibiotic Action of an *Aspergillus* Strain against *Mycobacterium tuberculosis**

In the course of investigations on the growth conditions of *Mycobacterium tuberculosis*¹, we have observed that contamination by an *Aspergillus* strain of cultures of *M. tuberculosis* human and bovine type resulted in a distinct inhibition of growth. Systematic experiments founded on this observation led to the preparation of filtrates from pure cultures of the mould, which were active against *M. tuberculosis* human and bovine type. A preliminary report on our results was presented to the Swedish National Society against Tuberculosis on October 1, 1943, in view of a recent communication by M. A. Soltys², which to report briefly our findings.

Our *Aspergillus* strain (the identification of which is not yet completed), when grown on a synthetic medium containing iron-, sodium- and magnesium salts, glycerine and certain nitrogenous substances such as asparagine, at pH 7.2 (phosphate buffer) and at 37° C., produces an antibiotic, which inhibits the growth of *M. tuberculosis* and of *Staphylococcus aureus*. No antibiotic is produced, when the mould is grown on a Czapek-Dox medium. Soltys states that his 'aspergillin' is inactive against *Staphylococcus aureus*, thus, the antibiotic present in our culture filtrates may be different from 'aspergillin'. The chemical properties so far investigated point to the non-identity of our product with the known antibiotics isolated from *Aspergillus* cultures, such as gliotoxin, helvolic acid or patulin. A detailed account of these investigations will be published elsewhere.

Inhibition of Mould Growth by *p*-Aminobenzoic Acid and the *n*-Butyl Ester

In tests conducted in these laboratories, *p*-aminobenzoic acid and the *n*-butyl *p*-aminobenzoate have shown definite reduction in rate of growth of three representative moulds (species of *Aspergillus*, *Penicillium* and *Byssosclamyces*) growing on Czapek-Dox agar medium, pH 4. Inhibition in the case of the acid was very marked (at least 50 per cent) at a concentration of 5.6 millimolar (mm) and a reduction could still be detected, in the case of *Aspergillus*, as low as 0.18 mm. The butyl ester proved more effective, greater than 70 per cent reduction being observed at 1.0 mm and a marked effect persisting down as low as 0.14 mm—the lowest concentration tested. In cases of the intermediate and lower concentrations of the free acid, the colonies remained regular in outline and maintained a steady though reduced rate of increase, concentrations 9.8 and 5.6 mm gave rise to very irregular and fluctuating growth. With higher concentrations of both substances, particularly of the *p*-aminobenzoic acid, an orange-brown pigmentation was observed both in the central felt and in the surrounding medium.^{1,2} With interest largely focused on the anti-sulphonamide and growth-factor effects of *p*-aminobenzoic acid and the fact that these are shown at extreme dilutions, it is not surprising that observations of inhibition by this substance have been relatively few. Woods³ has actually referred to a slight inhibition of bacteria at concentrations (unspecified) above 1 mm. Most workers have been concerned with lower maximum concentrations than this, although Meyer² does not report inhibition of *Mycobacterium tuberculosis* when working at concentrations as high as 7.3 mm. Tamura⁴ has, however, found inhibition of *Bacterium tularensis* at 0.5 mm and complete inhibition of growth after eight days at 1.0 mm. Johnson *et al.*⁵ found evidence of both stimulation and inhibition of luminescent bacteria according to the concentration of *p*-aminobenzoic acid in the different parts of the treated growth. Lee and Foley⁶ have made the interesting observation that raised temperatures can cause inhibition of bacterial growth by *p*-aminobenzoic acid at concentrations as low as 1 mm, as well as failure to show anti-sulphonamide action. Lavor and Ferguson⁷ record harmful effects on protozoa by concentrations of *p*-aminobenzoic acid (7.3–0.073 mm), comparable with those reported above as effective against moulds. Esters of *p*-aminobenzoic acid have also been recorded principally from the point of view of growth factor and anti-sulphonamide activity. These include simple alkyl esters^{8,9} and local anaesthetics of the same type^{10,11,12}. Kuhn *et al.*⁹ include some results with such esters. Their experience of the butyl ester differs from ours with fungi, in that they report it, together with the ethyl, lauryl and cetyl esters, as having no bacteriostatic effect with *Streptobacterium natarum* when studied up to approximately 12 mm. It is would, according to our experience, be at least in excess of the solubility of the butyl ester. Other compounds related to *p*-aminobenzoic acid could be mentioned. Both Hirsch¹³ and Kuhn *et al.*⁹ have reported inhibition by *p*-aminobenzamide, the former found it almost as active as sulphanilamide at comparable concentrations, the latter noted growth accelerations at greater dilutions (0.007 mm) but

50 per cent inhibition at 0.014 mm. Auhagen¹⁴ reports relatively weak sulphonamide-like inhibition with *p*-aminoacetophenone and *p*-aminobenzophenone. Other workers^{15,16} have studied a number of substituted *p*-aminobenzoic acids, and have found that according to the nature and position of the substituents, some of the compounds demonstrated sulphonamide-like bacteriostasis, some retained *p*-aminobenzoic acid properties, while others were practically inactive.

Such results as those reviewed above, taken with our own experience with moulds, suggest that more attention might be given to the inhibitory action of *p*-aminobenzoic acid and its derivatives. On one hand, increasing the concentration of *p*-aminobenzoic acid gives rise to definite inhibition. On the other, stimulation by sulphanilamide has been observed in low enough concentrations^{5,17}. Compounds like sulphanilamide and *p*-aminobenzoic acid might profitably be regarded as members of the same broad biochemical group possessing a similar 'pattern' of inhibitory properties, showing quantitative rather than qualitative differences in their toxic behaviour.

Evidence of its toxic properties raises the question as to the form in which *p*-aminobenzoic acid is likely to occur in the cell. It seems probable that some at least is built into a larger 'non-toxic' molecule. Recently the existence of 'bound' forms of *p*-aminobenzoic acid in naturally occurring material has been postulated^{18,19,20}. According to Blanchard's evidence²⁰ the amino group is likely to be involved in a peptide link. Ratner and others are reported²¹ as having isolated from yeast a polypeptide containing one molecule of *p*-aminobenzoic acid and some thirteen molecules of *l*-(+)-glutamic acid.

Further systematic investigations of *p*-aminobenzoic acid and related compounds are being conducted in these laboratories.

Production of Kojic Acid by *Aspergillus effusus* Tiraboschi

IN 1942 Wilkins and Harris¹ reported that culture media on which the mould *Aspergillus effusus* Tiraboschi (National Collection of Type Cultures, No. 973) had grown inhibited the growth of *B. coli* and *Staph. aureus*. It has been found that, under cultural conditions to be described, the whole of the antibacterial activity can be attributed to the production of kojic acid. Owing to the weakness of its antibacterial properties this substance is not generally regarded as an antibiotic, its detection as such was due to its relatively high concentration in the culture fluid. Attention is directed here to kojic acid as an antibiotic because it is a common product of mould metabolism and may account for the inhibitory properties of a number of moulds not yet investigated in detail. Recognition of this possibility may prove time-saving to other workers.

Kojic acid is stated by Yabuta² to be produced in a high yield from various carbohydrate sources by *Aspergillus oryzae*, *albus*, *candidus* and *nidulans*. It was obtained by Birkinshaw *et al.*³ from *Aspergillus parasiticus* and *Penicillium daleae* Zaleski. The latter authors deduced its production also by *A. effusus* Tiraboschi, *A. tamarii* and *A. flavus* from the production of a strong wine-red colour on treating the crude medium with ferric chloride, but it should be noted that the mould products claviformin (produced by at least four fungal species) and aspergillilic acid give a similar red colour with ferric chloride. The literature of kojic acid, up to 1934, has been reviewed by Barham and Smits⁴, who mention its antibacterial properties.

The mould was grown at 24°C in Erlenmeyer flasks on a medium of the following composition: maltose 40 gm, peptone 10 gm, malt extract 26 c.c., water 1 litre. The antibacterial activity of the medium, measured by the plate and cylinder method against *Staph. aureus*, reached a maximum at 12–14 days, thereafter diminishing rapidly. At that time yields of kojic acid averaged 8–9 gm per litre.

Tested by the dilution method, kojic acid completely inhibited the growth of a strain of the following bacteria at the concentration shown:

> 1	400	< 1	800	<i>Proteus</i> , <i>Salm. enteritidis</i> , <i>Bact. coli</i>
> 1	800	< 1	1600	<i>Salm. typhi</i> , <i>Staph. pyogenes</i> .
> 1	1600	< 1	3200	<i>Ps. pyocyanea</i> (2 strains)
> 1	3200	< 1	16400	<i>Ps. pyocyanea</i> (2 strains)

Unlike that of many other antibacterial substances, its potency was little affected by the number of bacteria present. A thousandfold increase in the size of the inoculum made little or no alteration in the inhibitory titre. Neither was the antibacterial activity reduced after incubation for three hours at 37°C in 50 per cent serum.

For testing toxicity to animal tissues, solutions of kojic acid were neutralized with sodium hydroxide to pH 6.8 (which does not diminish the antibacterial activity of the solution). The toxicity to cells *in vitro* was estimated by its effect on human leucocytes⁵. In a 1:100 solution the cells became sluggish or stationary in half an hour and were nearly all dead in three hours. In 1:200 the movement of the majority was arrested in two hours but the cells did not die. The preparation in 1:400 did not differ significantly from control preparations. Dr R. W. Ross informs us that a 1:400 solution did not interfere with phagocytosis by human leucocytes.

Sodium kojate produced characteristic signs when

injected into mice by any route in a sufficiently large dose. The mouse became prostrate, the legs and tail stretched out stiffly and the breathing slow and laboured, the coat was not roughened. After the largest doses there was slight irregular twitching of muscle groups and a lethal dose produced convulsions before death. The duration of sickness was proportional to the size of the dose, and even after prostration lasting for two or three hours, recovery, if occurred, was rapid and complete.

Friedemann⁶ described similar effects on dog rabbits and rats, and gave the toxic dose (intravenous) as 150 mgm per kgm and the lethal dose as 1 gm per kgm. The figures for mice are of the same order. In mice weighing from 20 to 23 gm 5 mgm injected subcutaneously, intraperitoneally or intravenously usually produced signs of toxicity, at 30–40 mgm killed, by mouth 20 mgm was without effect, 40 mgm produced illness and 80 mgm killed.

A Twenty-four Hour Pregnancy Test for Equines

IN 1928 the Aschheim-Zondek Test for the diagnosis of human pregnancy in urine was introduced¹. In 1930, B. Zondek proposed a modification of this test for the diagnosis of equine pregnancy in the blood and in the urine². The blood test is only feasible, however, between the 42nd and 125th days of pregnancy, after which the equine gonadotropin disappears from the blood³.

These pregnancy tests are based upon the gonadotropic reactions which have been classified (1926–5) as follows⁴:

Anterior pituitary reaction, I	oestrus reaction in the mouse and hyperaemia in the rat ovary, follicle hæmorrhage in the ovary of mouse and rabbit (blood dot)
Anterior pituitary reaction, II	corpus luteum formation in ovary of mouse, rat and rabbit
Anterior pituitary reaction, III	

Most characteristic is the follicle hæmorrhage appearing (as anterior pituitary reaction II) in the ovary of the mouse and rabbit, which has since been used for the diagnosis of pregnancy in man and equine. The reliability of pregnancy tests, based upon the gonadotropic reaction, is about 99 per cent. The only disadvantage of these tests is the long reaction time required: 6 days for the rat, 5 days for the mouse and 2 days for the rabbit.

It has recently been demonstrated that a reliable diagnosis of human pregnancy may be carried out within twenty-four hours, using the hyperaemic reaction of the infantile rat ovary (anterior pituitary reaction II). The test is based on the fact that within twenty-four hours (sometimes even two to six hours following the injection of human pregnancy urine) the ovaries of the infantile rat undergo a structural

peræmic reaction, accompanied by swelling, as already described in 1927⁴. This is the earliest stage gonadotropic reaction following the injection of gonadotropic hormone. It seemed possible that the pid method as applied to the urine of pregnant men might be applicable as well to the blood of egnant mares. In the latter, the diagnosis of early egnancy by a veterinarian is difficult, and on the her hand it is important to the breeder to recognize egnancy in its early stage in order to prevent ortion due to excessive work or strain.

The first thing to be established was whether the peræmia test is evoked by pregnant mare blood nadotropin as it is by human pregnancy urine nadotropin. The clarification of this point was of portance, as pregnant mare blood contains mostly e follicle-stimulating hormone and human pregnancy ne contains chiefly the luteinizing factor. We ind the hyperæmia test to be quite sensitive for e detection of minute amounts of human pregnancy ne gonadotropin, 1 hyperæmia unit (anterior utary reaction II) equalling 1 œstrus unit (anterior utary reaction I). Unfortunately, the hyperæmia st (anterior pituitary reaction II) is not so sensitive e the detection of small amounts of pregnant mare od gonadotropin, 1 hyperæmia unit (anterior utary reaction II) equalling as much as 10 œstrus its (anterior pituitary reaction I) and 3 luteiniza- n units (anterior pituitary reaction III) of preg- nt mare blood gonadotropin. The new method ures, therefore, 3-10 times the amount of hor- me administered in the earlier pregnancy test² for unes, but it has the advantage of giving clear-cut ults with 99 per cent reliability within twenty-four rs. It is possible to obtain a positive reaction h the hyperæmia test as early as 4-6 hours after ection of the equine gonadotropin. The reaction his early stage is positive, however, only in 33-50 cent of the animals, and whereas the positive re- ion indicates pregnancy, negative results cannot be luated. Furthermore, the faint pink colour of ovary, obtained after 4-6 hours, is not so con- eing as the dark red appearance after 12-24 hours efore, we prefer the 24-hour pregnancy test

Technique The mare or donkey is bled from the ular vein and 20 c.c. serum are sent to the labo- tory. If the specimen is sent through the post ew drops of phenol or preferably tricresol should added to the serum. In the laboratory four rats eeks old, 30-40 gm. in weight are injected as ows

R 1	20 c.c.	} twice daily, preferably at 2-4 hr intervals
R 2	15 c.c.	
R 3	10 c.c.	
R 4	0.5 c.c.	

1 is killed on the evening of the day of the first injection at least us after the first injection and 4 hours after the second injection 2 and R 3 are sacrificed on the following day, about 18-24 hours e the first injection.

4 is sacrificed 5 days after the first injection, after having received 0.5 c.c. serum for 4 consecutive days, that is, a total of 4 c.c. m

The test is positive if at least both ovaries of one he rats R 1-3 show a distinct red colour resembling t of the spleen or kidney. As a rule, all the rats t similarly. Autopsy of rat R 4 takes into con- ration vaginal œstrus and corpus luteum forma- : as in the original Aschheim-Zondek test and es for control purposes only. It detects all cases arly pregnancy or late pregnancy where the blood adotropin titre is lowered.

The hyperæmia test gives positive results with all e containing more than 250 IU pregnant mare

blood gonadotropin per litre. It may also be used for quantitative pregnant mare blood gonadotropin de- terminations since 1 hyperæmia unit, that is, the smallest quantity of serum evoking the rat anterior pituitary reaction II, equals about 1 IU. It facilitates the preparation of pregnant mare blood gonadotropin by making possible the bleeding of pregnant mares at the peak of hormone production.

A New Type of Phase Rule Solubility Test for Enzyme Purity

IN 1937 Kuhn and Desnuelle¹ prepared a highly purified specimen of Warburg's yellow enzyme, and as evidence of purity they pointed out that when ammonium sulphate was added to the solution the yellow colour and the protein began to come out of solution at the same salt concentration, and that the decrease in yellow colour and the decrease in protein content were parallel. They did not develop the test further, nor did they successfully apply it to the analysis of impure solutions.

From the work of Butler, Blatt and Southgate², Roche, Doriot and Samuel^{3,4}, and Jameson and Roberts⁵, it is clear that when increasing quantities of a precipitating salt are added to a series of protein solutions, the appearance of a new solid phase will cause a break in the curve relating concentration of protein in solution to salt concentration. Further, Jameson and Roberts pointed out that such breaks in continuity were in accordance with the phase rule.

It is the object of this account to show that an analysis of the effect of increasing quantities of a precipitating salt on a protein solution can be used as a purity test for any protein with an accurately measurable specific quality.

The enzyme solution used in these studies was a highly purified solution of pig liver esterase, and the precipitating salt was ammonium sulphate. Increasing quantities of salt were added to equal volumes of enzyme solution, and after precipitation had ceased the solutions were filtered and the filtrates analysed for enzyme and for protein. The test consists in plotting these latter quantities against one another and analysing the result.

From the work of Cohn⁶, we would expect a linear relationship between log solubility and ionic strength. It is therefore interesting to note that when plotted logarithmically, there is a double inflexion in the enzyme precipitation curve (graph 2), indicating the presence of two esterases the solid phases of which behave independently.

We can interpret graph 5 somewhat as follows. The fall in enzyme activity between A and B occurred before any protein precipitation took place, and is therefore probably due to denaturation on the air bubbles salted out by the ammonium sulphate. At B

the solution is saturated with respect to an impurity and the protein concentration decreases without any change in enzyme concentration to C , where the solution becomes saturated with respect to the enzyme. Between C and the origin the concentration of the impurity decreases with respect to that of the enzyme and the curve gradually straightens. The inflexion due to the precipitation of the second enzyme does not occur, probably because the activities of the two enzymes expressed as enzyme units per milligram of protein nitrogen are too close to show as a difference in slope.

If we assume Cohn's equation⁶ and let S_I and S_E , β_I and β_E , and k_I and k_E , be the solubilities, intercept constants, and slope constants of the impurity and of the enzyme respectively, and if I be the ionic strength, we have

$$\log S_I = \beta_I - k_I I \quad (1)$$

$$\text{and } \log S_E = \beta_E - k_E I \quad (2)$$

$$\therefore S_I = e^{(\beta_I - k_I I)} \quad (3)$$

$$\text{and } S_E = e^{(\beta_E - k_E I)} \quad (4)$$

Now since the protein concentration P at any point on graph 5 between C and the origin is equal to the sum of the protein solubilities, the equation to graph 5 must be

$$P = e^{(\beta_I - k_I I)} + \frac{1}{K_E} e^{(\beta_E - k_E I)} \quad (5)$$

where the conversion constant K_E is equal to the activity of the pure enzyme expressed as enzyme units per milligram of protein nitrogen.

Equation 5 expresses the relationship between the enzyme and the impurity, and can be used to calculate the subsequent purification procedure.

It is clear that in the case of a pure substance graph 5 would be a straight line passing through the origin.

It is a pleasure to express our indebtedness to both Dr G S Adair and Dr D W G Style for their invaluable advice on many points.

Structure of the Photon

By analogy with the existence of both positive and negative electric charges, one may envisage the possibility of the existence of negative as well as positive mass. The non-appearance of such particles can be readily explained, but in at least one case the hypothesis leads to useful deductions.

Consider a particle of mass and charge both equal to those of the electron, but opposite in sign. In free space the behavior of a doublet consisting of an electron and this particle (termed provisionally the a-tron) shows considerable similarity to that of a photon.

When the electron and a-tron coincide there is no resultant charge or mass, no internal effects are observed and to all intents and purposes the doublet is non-existent. If the two particles are separated by a suitable amount of energy a force of attraction arises which accelerates the electron towards the a-tron, and the latter away from the electron (due to its negative mass). The doublet as a whole travels forward with a limiting velocity the velocity of light. The separation of the two particles determines the energy E of the doublet, but not its velocity.

The 'effective' mass M of the doublet in motion is determined by its energy E ,

$$m = E/c^2$$

Its momentum p ($p = E/c$) can be lost in part on collision with matter (Compton effect), with changing the limiting velocity c .

In free space the doublet behaves as a unit, the presence of a positive gravitational mass it accelerated bodily towards the latter. It cannot be subdivided without losing its fundamental properties and this property it shares with the photon.

To a stationary observer the emission of a doublet by a moving body results in a change in wavelength due to the 'carry-on' of the electron, which is emitted after the emission of the a-tron (Doppler effect).

On interaction with matter, the doublet may appear as a unit, for example, the a-tron may

neutralized by an electron, thereby freeing the electron constituent of the doublet, together with a corresponding amount of energy (photo-electric effect)

The electromagnetic wave properties of the photon are paralleled by those of the probability waves of the doublet. The close analogy between them is demonstrated, for example, by the similarity in the laws of interference of electronic probability waves and of electromagnetic waves (electron and X-ray diffraction)

A photon of energy E has a wave-length $\lambda_p = hc/E$. A doublet of this energy has a de Broglie probability wave-length $\lambda_b = h/mc = hc/E$ (from equation 1). Thus the de Broglie probability wave-length of the doublet equals the electromagnetic wave-length of the photon in free space. Similarly, the velocity of the de Broglie waves ($u = c^2/v = c$) equals that of light. In a medium of refractive index other than unity this conclusion requires modification.

In free space the doublet can thus be represented by a sinusoidal probability wave, of wave-length λ and travelling with velocity c . The square of its amplitude at any point is proportional to the charge and mass at that point.

The electric and magnetic fields associated with the photon arise, not from this sinusoidal variation in electric charge, but from the magnetic moment due to electron (and a-tron) spin. At rest, the magnetic moments of electron and a-tron coincide and neutralize one another. In motion it is assumed that they are perpendicular to the direction of motion. At any point the sinusoidal variation in electric charge density gives rise to a corresponding variation in the magnetic moment (which is proportional to it), and hence to that of both magnetic and electric fields.

The direction of magnetic moment of the doublet may be indeterminate around the axis of propagation. It may be parallel to a given direction, etc. In the first case, the waves are unpolarized, in the second they are linearly polarized. Corresponding to the laws relating to the polarization of light are those relating to the spin of the electron and a-tron. Further consideration of a duality of positive and negative masses appears capable of furnishing information on the nature of the electric field.

Polymorphism of Bismuth Trioxide

From thermal analyses, Guertler¹ concluded that bismuth trioxide, Bi_2O_3 , existed in two forms, one stable above 704°C and one stable below this temperature. He was not able to prepare the high-temperature modification even by quenching. From the smoke of burning bismuth, Sillén² prepared a second form of bismuth trioxide, which was proved by X-ray analysis to be different from the ordinary form. This new phase was called $\beta\text{-Bi}_2\text{O}_3$ and the ordinary form $\alpha\text{-Bi}_2\text{O}_3$, and it was assumed that $\beta\text{-Bi}_2\text{O}_3$ corresponded to Guertler's high-temperature form. Schumb and Rittner³ have also prepared β -form and shown that it is transformed to the α -form below 710° . However, they believe that the transitions $\alpha\text{-Bi}_2\text{O}_3 \rightarrow \beta\text{-Bi}_2\text{O}_3$ and $\beta\text{-Bi}_2\text{O}_3 \rightarrow \alpha\text{-Bi}_2\text{O}_3$ are rather slow reactions, and that the transition

point observed by Guertler was quite a different phenomenon, due to contamination of the molten oxide by the crucible employed.

Now if bismuth trioxide is heated to above 700° in a crucible of a resistant material and then allowed to cool, the mass is first seen to darken and then suddenly to glow, which strongly indicates the presence of a transition point. We have tried to investigate this transition under such conditions that contamination was practically excluded. A rather large quantity of pure bismuth trioxide was heated (in a platinum crucible) for about thirty minutes to below its melting point. The temperature was measured by means of a thermocouple inserted directly in the mass. The cooling curve very clearly shows a transition point at about 700° (see accompanying graph). Since the careful work of Schumb and Rittner has shown that the transition point of $\beta\text{-Bi}_2\text{O}_3 \rightarrow \alpha\text{-Bi}_2\text{O}_3$ is at about 710° , our experiments appear to indicate, in accordance with Guertler's, that the transition is more rapid than Schumb and Rittner have suggested.

When Guertler fused bismuth trioxide in a porcelain crucible, he obtained a new substance which he considered to be a third modification of the trioxide. Sillén also prepared this substance and found that it was isomorphous with a synthetic compound with a body-centred cubic cell containing $\text{Si}_2\text{Bi}_{12}\text{O}_{40}$. The latter seems to be built up by spheres of composition $\text{SiBi}_{12}\text{O}_{20}$ with Si in the centre. Similar compounds were prepared from Bi_2O_3 and Al_2O_3 or Fe_2O_3 . Their composition may be $\text{Me}_2\text{Si}^{3+}\text{Bi}_{12}\text{O}_{39}$.

Schumb and Rittner have prepared a third form of bismuth trioxide called by them $\gamma\text{-Bi}_2\text{O}_3$. Powder photographs and density measurements indicated a body-centred cubic cell containing $\text{Bi}_{12}\text{O}_{39}$. Though this cell is very similar to the body-centred cubic cell determined by Sillén, Schumb and Rittner do not consider the crystal structure to be the same. They hold that the differences in ionic radii between Bi^{3+} and the Me ions in $\text{Si}_2\text{Bi}_{12}\text{O}_{40}$ and similar compounds is too large to allow Bi^{3+} to be substituted for the Me ions.

We have prepared the $\gamma\text{-Bi}_2\text{O}_3$, following the method of Schumb and Rittner. Their analyses did not entirely exclude the possibility that some of the bismuth is pentavalent, and the formula $\text{Bi}_{12}\text{O}_{40}$ did not seem improbable by analogy with $\text{Si}_2\text{Bi}_{12}\text{O}_{40}$. We therefore analysed for Bi^{5+} , but within the limits of error we found none. Consequently, the unit cell of $\gamma\text{-Bi}_2\text{O}_3$ probably contains $\text{Bi}_{12}\text{O}_{39}$. Since the work of Sillén, Aurivillius has investigated a number of metal bismuth oxides seemingly isomorphous with $\text{Si}_2\text{Bi}_{12}\text{O}_{40}$. A summary is given below. Hitherto no mono- or divalent ions have been found to enter the central positions of Si^{4+} . The table shows that the lattice dimensions grow larger when the Si^{4+}

ions are replaced by larger cations and that even Ce^{4+} can be substituted for Si^{4+} . Unlike Schumb and Rittner, we therefore think that even Bi^{3+} can enter the central positions, though this will imply only fourfold co-ordination of oxygen ions around the central bismuth ions. As the unit cell of $\gamma \text{Bi}_2\text{O}_3$ contains 39 oxygen atoms, it is necessary to assume vacancies in the oxygen lattice.

Cube edges of various Me-Bi-O compounds of type $\text{Si Bi}_2\text{O}_{10}$

Bottom Deposits of the Red Sea

DURING the Egyptian Preliminary Expedition to the northern Red Sea in the R.R.S. *Mabaluth* during 1934-35, which I accompanied, some sixty bottom-samples were collected, in particular from the three differently constituted areas, the Gulf of Suez, the Gulf of Aqaba and the Red Sea proper^{1,2}. The mechanical composition and mineralogy of the bottom sediments were recently examined in the Department of Geology, Faculty of Science, Cairo.

The Red Sea is unique among the seas of the world in the fact that no permanent streams flow into it, and that only winds, mostly north-westerly, and occasional rain-torrents contribute material to its bottom. The sea is probably unique also for the very irregular bottom topography (excluding the Gulf of Suez), hence the nature and distribution of its bottom deposits are unmatched in other seas.

The sediments are coarser and better sorted, when they are secured from shallow or sloping bottoms (being finer in basins than on ridges and slopes) or from near land masses (including submarine ridges)³. The topography of the bottom seems to be the important factor in determining the physical constitution of the deposits. The irregular topography of the bottom gives rise to variety in the sediments. Contrasts appear between the deposits of the shallow and smooth Gulf of Suez, the deeper Gulf of Aqaba and the very irregular Red Sea proper. The Gulf of Suez, because of its flat bottom, has deposits with but little variation in their statistical data, in contradistinction with deposits on the very irregular bottom of the Red Sea, which have rapid changes in the corresponding statistical constants. The difference in environment is also shown by the fact that the sediments of the Gulf of Suez, though of shallow origin, are finer and less sorted than those of the Gulf of Aqaba or the Red Sea shallow environments. The peculiarity of the Gulf of Suez is also reflected in the mineralogy of its sediments, which are much richer in authigenic pyrites than either the Gulf of

Aqaba or the Red Sea. The Gulf of Suez sediments are, in fact, comparable with normally sorted sediments from continental shelves, the Gulf of Suez is itself a shallow flat shelf filled with surface water of the Red Sea and descending at its mouth abruptly to a depth five times greater than its own. It is to be noted that the chemistry of the bottom deposits showed contrast in the three main regions investigated⁴.

The mineralogy of the sediments is uniform over the different provinces and thus contrasts with that of the usual basins of deposition. Local variations are, however, caused by contamination from local source rocks or variation in the environmental conditions of deposition⁵. Such uniformity in the mineralogy of the Red Sea bottom sediments, which are mainly carried by wind, and the absence of sedimentary petrographic provinces, are the main characteristics of wind-borne detritals. The conclusion of Sujkowski, who examined bottom deposits from the middle and south-eastern parts of the Sea, that the characteristic of the deposits, because of the absence of any chemical decomposition and lack of water transportation, is the presence of the easily weathered, coloured minerals and the common rock-forming minerals of crystalline rocks in abundance in a fresh state⁶, are invalid as he overlooked the factor of provenance. The recent dunes of the great African Sahara, where conditions that favour mechanical disintegration rather than chemical decomposition of source rock prevail, but where sediment and not crystalline rocks dominate, contain a totally different assemblage (poor in the common rock-forming minerals: pyroxenes, amphiboles, micas and feldspars) from that of the Red Sea⁷. On the other hand, the Nile sediments, which are water-borne, gave an assemblage of minerals with the same characteristics as those of the Red Sea bottom deposits. Both formations, though of two different modes of origin, are remarkable examples of the richness of recent sediments (derived from crystalline rocks) in vulnerable minerals. The statement of White⁸ that the wind-borne sands contain less frequent heavy minerals than water-borne sands, and that the heavy minerals are less frequent in larger deserts than in smaller desert areas, is invalid as he did not take into account the factor of provenance in this case also.

The mineral assemblage of a sediment depends, in fact, on the following three main factors, which should be collectively taken into account when the nature of the assemblage is to be explained: (1) nature of distributive rocks, (2) type of weathering and mode of transportation, (3) post-depositional processes, leading to simplification of detrital grains¹.

The mineralogy of the clay fractions of the bottom deposits is, at present, under investigation.

IDES OF THE ATLANTIC OCEAN

PROF J PROUDMAN, professor of oceanography in the University of Liverpool, delivered the George Darwin Lecture at the Royal Astronomical Society on October 13, 1944, the subject of his lecture being "The Tides of the Atlantic Ocean" (*Ion Not Roy Ast Soc*, 104, 5, 244, 1944).

Prof Proudman gave a short history of the problem, starting with Whewell, who published the first tidal charts in 1833, which were based on reasoning of a largely non-dynamical character. Whewell's intuitions that the tides of the Atlantic were generated in the Southern and Pacific Oceans, which were rejected and which Whewell himself had abandoned by 1848, continued, unfortunately, to be treated for a long time in text-books. In 1874 Ferrel calculated, on dynamical principles, what the tides would be in canals along parallels of latitude stretching from one side of the Atlantic to the other.

He thought that there might be an approach to conditions of resonance for a canal between Ireland and Newfoundland, and if a dyke extended from the Cape of Good Hope to the coast of South America, the tides in the North Atlantic would probably be very nearly the same as they actually are. In 1900 Morris took up Ferrel's work, and four years later instructed charts of co-tidal lines for all the oceans were issued, but as Proudman points out, his work involved a number of serious errors, among which may be noticed a mathematical mistake involving an error of three hours in the times of high water, the neglect of the resonance of transverse oscillations for the North Atlantic, lack of consideration of the effect of water in neighbouring regions, and failure to give adequate consideration to the dynamical effects of earth's rotation.

In 1910 Poincaré discussed the energy implications of progressive waves, and in applying his principle of the influx of energy into any region and the forces which must balance it, he concluded that, for the arctic seas, the dissipation of energy by the friction of tidal currents on the sea bottom was always negligible, that the work done against the separating force was also negligible, and that the loss of energy out of the region was insignificant on account of the smallness of the Bering Strait. He therefore deduced that the arctic tides do not consist of a wave progressing from the Atlantic, but, as Ferrel showed in 1918 and Jeffreys in 1923, friction is by no means negligible in shallow seas, and Poincaré's arguments could not be maintained.

A brief reference is made to Sterne's co-tidal lines, which are not based on dynamical principles, but on observation, and then Defant's work is considered at length. Defant abandoned his work of 1914 and confined his attention to the neighbourhood of the central line of the ocean and also to part of the Atlantic south of Iceland. He started assuming that the rotation of the earth does not affect the tidal conditions on the central line, that the transverse generating forces do not affect tidal conditions on the central line, and that there is no dissipation of energy to the south of Iceland. He considered two phases, differing by a quarter period, such that they agree with observations at the Azores and Tristan da Cunha, the node of one phase coinciding with the loop of the other, and his results were in good agreement with the observations on these islands. Although Defant's assumptions cannot be regarded as anything more than rough approxima-

tions, conditions on the central line can be largely accounted for by means of longitudinal oscillations.

Prof Proudman then turned to the results of his own researches, which are purely dynamical and are concerned with a study of a region of the Atlantic bounded by two parallels of latitude, those of 45° N and 35° S. He supposes that we are given either (1) the general conditions to be satisfied along the coasts and the actual meridian-components of currents across the bounding parallels, or (2) the general conditions to be satisfied at the coasts and the actual tidal elevations on the bounding parallels, or (3) the general conditions to be satisfied at the coasts and the actual meridian-components of the currents on one bounding parallel and the actual elevations on the other bounding parallels. Then the tidal elevations and currents are mathematically determinate all over the region considered, including their values on the coasts. As we do not know the actual currents or the actual elevations or the bounding parallels, but we know the coastal elevations, the problem is considered the other way round. Given the general conditions along the coasts and the actual values of coastal elevations, the tides are mathematically determinate over the whole region considered, and Prof Proudman solves the problem by considering a number of subsidiary problems of a different type, but limits of space prevent a detailed account of these, and a short summary of his work must suffice.

Selecting the parallel of 35° S as the one along which certain conditions are prescribed, and taking the elevations and meridian components of current to be zero along this parallel, but allowing for all the generating forces, one particular solution is obtained. While the resulting oscillation is small in the South Atlantic, there are larger amplitudes in the North Atlantic, and a large co-tidal area exists here. A second particular solution is an oscillation which Prof Proudman calls a north-going Kelvin-wave, and corresponds to currents along the meridians and to elevations, both of which increase exponentially towards the west. Considerable complications are produced by the curvature of the earth along the meridians, by variations in the width of the oceans and by variations in depth. A third solution gives a south-going Kelvin-wave, and again the currents in latitude 35° S are along the meridian, but in this case both the elevations and currents increase exponentially towards the east. By assuming that the transverse currents follow a sine-distribution from coast to coast, two other solutions, called the north-going and the south-going Poincaré-wave, are obtained, and in these cases the amplitudes are small in the centre of the ocean.

The problem is to assign an amplitude and a time-origin to each Kelvin- and Poincaré-wave, so that when the four are added to the forced oscillation, the coastal elevations in the synthesis will agree with observations so far as possible. Prof Proudman has made the sum of all the waves agree with observation at four points on the coasts, and he has chosen two of these points in latitude $32^{\circ} 5' S$ and the other two in latitude $7^{\circ} 5' S$, that is, south of the Gulf of Guinea and Cape San Roque, where the major irregularities of the basin begin. The north-going Kelvin-wave is the most important with an amplitude of 52 cm and a high-water time of 1.8 hr at the south-west corner of the region considered. The south-going Poincaré-wave is the next most important, it has an amplitude of 35 cm and a high-water

time of 9.1 hr at the south-west corner. The other two free waves have each an amplitude of 22 cm at the south-east corner, and the high-water time of the south-going Kelvin-wave at this point is 10.8 hr, and that of the north-going Poincaré-wave 0.5 hr. The agreement with observation is good as far as 5° S latitude, but considerable divergences set in afterwards. Part of this divergence may be due to not including a sufficient number of Poincaré-waves, and Prof Proudman hopes to obtain better results by including more of these waves than he has done in the present investigations.

PLANT DISEASE AND THE WEATHER

CLIMATE exerts an important influence on the spread and severity of plant disease—an influence long recognized, though not yet fully investigated. Some recent progress in this field was discussed in a symposium arranged by the Department of Plant Pathology of the West of Scotland Agricultural College at Auchincruive on November 8. The meeting was attended by the advisory pathologists for Scotland, the staff of the Plant Pathology Service of the Department of Agriculture for Scotland, members of the College staff, of the University of Glasgow and the Hannah Dairy Research Institute.

Dr. C. E. Foister, head of the Plant Pathology Service of the Department of Agriculture for Scotland, opened by a short review of progress since the Conference of Empire Meteorologists in London in 1929. It becomes increasingly clear that records taken with ordinary meteorological exposure do not provide the pathologist with all the data he requires. It is necessary to study weather within the crop, and to follow up such information by investigations with artificially controlled conditions. Physiological races of fungi, moreover, may react differently to weather conditions. The distribution and occurrence of yellow rust of wheat in Scotland, for example, suggests the existence of different races varying in their reaction to environmental factors. Several parasitic fungi, common in England and Wales, are rare or unknown in Scotland, or confined to certain areas there. They include *Puccinia tritici*, *Septoria tritici*, *Rhynchosporium secalis*, *Phytophthora cactorum*, *Diaporthe umbrina*, *Heteropeltella anturhina* and the Dutch elm disease.

The rhododendron bug has twice invaded Scotland, but has failed to establish itself. How far are these apparent absences due to weather?

Dr. John Grainger, head of the Plant Pathology Department at Auchincruive, considered the aerial climate, the soil climate and the major effects of weather, with special reference to work carried out at Auchincruive in 1944. He showed how daily averages of aerial temperature and humidity inspired further work, but only continuous records within the crop revealed true phenological relationships. Chocolate spot of the field bean, bean leaf spot (*Ascochyta fabae*), and *Erysiphe graminis* on oats, all showed some increase of attack with rising relative humidity, but the real correlation was between disease intensity and the number of hours per day with complete saturation. Drain-gauge studies at Auchincruive have shown the large amount of rainfall evaporated from the soil. One aspect of aerial climate often neglected is that of conditions of

storage for seed, it might be possible to provide conditions under which the parasites lose the viability before the seed. The major effects of weather are mainly important in so far as they transport fungal spores from one area to another. It has been found, however, that large teleutospores of some rust fungi are not carried more than a few yards by wind. Climate cannot, of course, be controlled, but the practical value of weather studies lies in the following points: (1) its value in life history and mycological studies, (2) its help in raising immune or resistant crop varieties, (3) virus infected crops should be rogued within such temperature limits as the symptoms are not masked, (4) the time of farming operations can be adjusted to avoid some infections, (5) excessive atmospheric humidity may possibly be controlled in some parts of Scotland by adequate drainage; (6) conditions of seed storage may be devised to minimize seed-borne disease, (7) growers may be advised when to spray in order to eliminate disease epidemics.

The role of weather as direct pathogen in causing frost damage to fruit blossom was discussed by Dr. C. E. Cornford, of the Midland Agricultural College. Field experiments with orchard heaters were described which showed that the hot air they supplied was chilled or warmed by several other agents. These included katabatic winds, altitude, the amount of cloud, the presence or absence of large dense grass exposed to the sky, the humidity of the air and the dryness of the trees and soil.

Dr. B. T. Cromwell (Auchincruive) presided over the discussion which followed. Mr. A. Hedderley (Edinburgh) contrasted the epidemic of yellow rust in 1919 with its scarcity in 1944. The problem is complicated by the long growing-period of winter wheat. Dr. Mary Noble (Edinburgh) and Dr. Elizabeth Grant (Aberdeen) then contributed, and it appeared that winter wheat was generally much more susceptible than spring wheat in Scotland, and the severity of epidemics when they did occur was such that further detailed experiment was advisable. Dr. Grainger answered questions on frost damage in Dr. Cornford's absence. His own experience showed that oil heaters only raised the temperature of the air in their immediate neighbourhood by about 4° F. Evaporation from the buds lowered their internal temperature 2° F, giving a net internal rise of about 2° F. Tripping with humidified heating raised the air temperature near the source by 2° F, without internal cooling, thus resulting in a very considerable saving of fuel. Mr. Dovaston (Auchincruive) raised the question of avoiding grass cover in orchards subject to frost damage, but Dr. Cromwell and Mr. R. D. Reid (Auchincruive) held that grassing down was a very practical method of maintaining nutritional balance of the trees, particularly with regard to nitrogen.

Dr. Foister, Dr. Cromwell and Mr. Reid considered the occurrence of *Cladosporium* mould in tomato glasshouses. The disease was often more severe in low-lying houses on sandy soil than in higher situations on heavy soil, the factor of humidity did not seem to be the only one, and the admission of ultraviolet rays through 'Vita' glass did not eliminate the fungus. This discussion again pointed to the need for more detailed work. Dr. R. Laird (Ayrshire) mentioned that *Ascochyta fabae* and chocolate spot were more severe in low-lying, sheltered fields, but remembered that certain periods when these diseases were spreading were characterized by hot, dry days. Dr. Grainger explained, however, that long periods of complete

uration occurred during the nights at that time—act which again stressed the value of continuous records within the crop. Dr C L Whittles (Auchinave) urged the necessity for continuous records of the soil factors, as pH, water content, conductivity and oxidation-reduction potential.

INDUSTRIAL DEVELOPMENT IN AUSTRALIA

THE paper "Scientific Aspects of Australia's Industrial Development", which Mr G B Gresford read before the Royal Society of Arts on January 16, naturally covers a good deal of ground common with the annual reports of the Commonwealth's Council for Scientific and Industrial Research, though the account is rather more up to date, and in a larger setting. Mr Gresford referred particularly to the recent plans of the Australian wool industry, stimulated no doubt by competition from artificial fibres, for a large expansion of scientific research. Part of the large sum which the Australian Wool Board proposes to raise by increasing the levy on growers of wool would be spent by the Council for Scientific and Industrial Research on biological and textile research, and part would go towards economic research and publicity. Whether or not the opinion is justified that fundamental research will lead to the improvement of wool yield and quality, the cheapening of processing and the development of new and better fabrics so that wool can more than hold its own, the link between science and the wool industry becomes closer.

After a reference to research in connexion with new crops such as wheat, and the significance of the developments in the field of nutrition and developments in the manufacture of fertilizers and sulphuric acid, Mr Gresford mentioned particularly the part science has played in the development of the mining and metal industries. Investigations on flotation, and particularly the discovery of the collecting properties of sodium ethyl xanthate for the sulphide minerals, have led to the present high recoveries of lead and zinc in the flotation sections of the mines. The work at the University of Melbourne on fundamental physical chemistry of the flotation process, which ten years before the War was financed by a group of Australian mining companies, is now partly carried on by the Council for Scientific and Industrial Research. Work in new fields has suggested possible extensions of the flotation process to the concentration of new minerals. Mr Gresford also referred to the continuous lead refining process for dressed steel bullion evolved by the staff of the Broken Hill Associated Smelters as a striking example of the application of physical chemistry to an industrial process.

The paper industry, and particularly the development of processes for a wide range of papers from eucalyptus woods by a chemical or mechanical method, provides a further example of the solution by scientific research of a problem deemed intractable.

which has now made the Australian industry almost entirely independent of imported materials. Turning to the universities as sources of supply of scientific personnel for industry, Mr Gresford said that the demand at present greatly exceeds the supply, and if maintained it will involve a corresponding expansion of the universities. Plans have

been made for a considerable expansion of Government research activities, but further expansion of research in industry is desirable. So far, scientific exploration has not revealed any sources of flow oil in Australia, attention has not been given to the synthetic production of liquid fuels from coal, although the brown coal deposits of Victoria are very similar to those used in Germany for this purpose. Organic chemical industry on a large scale has scarcely been started and the development of the chemurgic industries, utilization of agricultural wastes, alkaloids and essential oils are other fields awaiting the application of scientific methods in Australia.

SYNTHESIS OF BIOTIN

A SYNTHESIS of biotin by S. A. Harris, D. E. Wolf, R. Mazingo, R. C. Anderson, G. E. Arth, N. R. Easton, D. Heyl, A. N. Wilson and K. Folkers, of the Research Laboratory of Merck and Co., Inc., has recently been described (*J. Amer. Chem. Soc.*, **66**, 1756, 1944).

The process involves several steps. L-cystine is reduced in liquid ammonia with sodium and coupled with chloroacetic acid to give β -(carboxymethylmercapto)-alanine, subsequent benzoylation and esterification of which yielded the dimethyl ester of N-benzoyl- β -(carboxymethylmercapto)-alanine. The diethyl ester was obtained by condensing thioglycolic ester with the ethyl ester of N-benzoyl- β -chloro-alanine, derived from N-benzoylserine by esterification and chlorination with thionyl chloride. The dimethyl ester was treated with sodium methoxide in methanol to give the sodium salt of 4-benzamido-3-ketotetrahydro-2-thiophenecarboxylic acid methyl ester, racemization occurring during the reaction. The sodium salt was hydrolysed and decarboxylated in an aqueous acetic acid-hydrochloric acid solution to give 4-benzamido-3-ketotetrahydrothiophene. The valeric acid side-chain was introduced by means of an aldehyde prepared from glutaric acid. The acid was converted in turn to glutaric anhydride, glutaric acid monomethyl ester, γ -carboxymethoxybutyryl chloride, and finally to methyl γ -formylbutyrate by a Rosenmund reduction.

The aldehyde ester, condensed with the ketone, 4-benzamido-3-ketotetrahydrothiophene, with piperidine acetate as catalyst, yielded the methyl ester of 4-benzamido-3-keto- $\Delta^{2,5}$ -tetrahydro-2-thiophenevaleric acid, which reacted with hydroxylamine hydrochloride in pyridine to yield the methyl ester of 4-benzamido-3-oximino- $\Delta^{2,5}$ -tetrahydro-2-thiophenevaleric acid, reduction of which by zinc dust in an acetic acid-acetic anhydride mixture gave two compounds, one the methyl ester of 3-acetamido-4-benzamido-4,5-dihydro-2-thiophenevaleric acid. Hydrogenation of this over a palladium catalyst and fractional crystallization of the products gave two racemates of the methyl ester of 3-acetamido-4-benzamidotetrahydro-2-thiophenevaleric acid. Each of these was hydrolysed with barium hydroxide, and subsequent treatment of the products with sulphuric acid gave the corresponding sulphates of the 3,4-diammotetrahydro-2-thiophenevaleric acids.

The acids, when treated with phosgene, yielded two racemates of hexahydro-2-oxo-1-thieno[3,4]imidazole-4-valeric acid, which will be called *dl*-biotin, and *dl*-allobiotin. The *dl*-biotin was resolved through its esters with L-mandelic acid to give biotin.

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Saturday, March 10

INSTITUTE OF PHYSICS (SOUTH WALES BRANCH) (in the Physics Department, University College, Swansea), at 2.30 p.m.—Inaugural Meeting Dr C Sykes "Physics in Metallurgy" *

Monday, March 12

FARMERS' CLUB (at the Royal Empire Society, Craven Street, Strand, London, W C 2), at 2.30 p.m.—Mr Geoffrey Crowther "An Economist Looks at British Agriculture"

ROYAL INSTITUTE OF CHEMISTRY (in the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 4 p.m.—Annual General Meeting

SOCIETY OF CHEMICAL INDUSTRY (YORKSHIRE BRANCH) (in the Metropole Hotel, King Street, Leeds), at 6.15 p.m.—Mr S. W. Butterworth "Flour", Mr E. F. Eaton "Colours in Foods"

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the INSTITUTION OF RUBBER INDUSTRY) (in the James Watt Institute, Birmingham), at 7 p.m.—Dr W. J. S. Naughton "Rubber Chemicals—Past and Present Influence on Synthetic Rubber"

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S W 7), at 8 p.m.—Mr Christopher Sandeman "North-eastern Highway of Peru"

Tuesday, March 13

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5.15 p.m.—Sir Henry Dale, O.M., Pres. R.S. "Nerve Endings and Chemical Transmitters", (2) "Adrenaline and Acetylcholine", Adrenergic and Cholinergic Nerves"

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Discussion on "Colour Television" (to be opened by Mr L. C. Jesky)

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Prince's Gate, South Kensington, London, S W 7)—Dr H. Baines Presidential Address

Wednesday, March 14

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Mr J. H. O. Bunge "The Thames Barrage and its Importance in the London Reconstruction Plans"

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP, MICROBIOLOGICAL PANEL) (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 2.30 p.m.—Miss E. M. L. Elliot "Bacteriological Aspects of the Laboratory Examination of Meat", Mr L. B. A. Grace "Aspects of Practical Meat Inspection"

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 3 p.m.—Anniversary Meeting

ROYAL METEOROLOGICAL SOCIETY (in the small Physics Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S W 7), at 4.30 p.m.—Major H. C. Gunton "Report on the Phenological Observations in the British Isles from December 1943 to November 1944"

INSTITUTE OF PETROLEUM (in the Lecture Theatre of the Royal Society of Tropical Medicine, 26 Portland Place, London, W 1), at 4.30 p.m.—Thirty-second Annual General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (TRANSMISSION SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Mr W. Kidd and Mr E. M. S. McWhirter "Operational Control of Electricity Supply Systems"

SOCIETY OF CHEMICAL INDUSTRY (SOUTH WALES SECTION) (joint meeting with the ROYAL INSTITUTE OF CHEMISTRY) (at the Technical College, Newport, Mon.), at 6.45 p.m.—Dr H. E. Crossley "The Nature and Significance of the Inorganic Substances in Coal"

Thursday, March 15

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 2.30 p.m.—Prof E. K. Rideal, F.R.S. "Reactions in Monolayers" (Liversidge Lecture)

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5.15 p.m.—Sir Lawrence Bragg, F.R.S. "Some Physical Problems of the Solid State"

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 8 p.m.—Mr L. Dudley "The Development of Stereoscopic Photography and Radiography"

Friday, March 16

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Mr J. Z. Young "The Structure, Degeneration and Repair of Nerve Fibres"

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 5 p.m.—Special General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Dr G. F. Tagg "The Temperature Compensation of Indicating and Recording Instruments"

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St James's Park, London, S W 1), at 5.30 p.m.—"Invention after the War" (to be introduced by Mr Harold Sinclair, Mr E. W. Moss and Mr H. W. Cadman)

Saturday, March 17

BIOCHEMICAL SOCIETY (at the Middlesex Hospital Medical School, London, W 1), at 2 p.m.—Annual General Meeting

INSTITUTION OF MECHANICAL ENGINEERS (GRADUATES' SECT) (at Storey's Gate, St James's Park, London, S W 1), at 3.30 p.m.—Mr A. H. Lloyd "British Machine Tools during the War" (An Lecture)

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GR) (at 16 Prince's Gate, South Kensington, London, S W 7)—Mr I. Chilton First Renwick Memorial Lecture

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on before the dates mentioned

LECTURER IN ELECTRICAL ENGINEERING for National Diploma Higher National Certificate Courses in the Crumlin Mining and Technical College—The Director of Education, County Hall, New Mon (March 16)

LECTURER (full-time) IN ENGINEERING SUBJECTS—The A. Principal Technical Institute, Clowne, Chesterfield (March 17)

ASSISTANT BIOCHEMIST—The House Governor, General Hospital, Birmingham, 4 (March 17)

ASSISTANT CIVIL ENGINEER (permanent) by West Ham Co Borough to take charge of the Civil Engineering Section of the Borough Engineers Department—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room Sardina Street, Kingsway, London, W C 2 (quoting Reference E 1426 XA) (March 20)

METALLURGIST of Degree standard by large Engineering concern in S.E. England—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room Sardina Street, Kingsway, London W C 2 (quoting Reference F 3537 XA) (March 21)

LECTURER (non-resident) IN GEOGRAPHY, with some MATHEMATICS—The Principal, Diocesan Training College, Salisbury (March 2)

LECTURER (full-time) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, and a SCIENCE LECTURER (full-time) IN THE DEPARTMENT OF BUILDING, of the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool, 1 (March 24)

TECHNICAL INSPECTOR AND GRADER IN THE MILK PRODUCT DIVISION of the Ministry of Food at Colwyn Bay—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardina Street, Kingsway, London, W C 2 (quoting Reference No F 3397 A) (March 26)

LECTURER IN SPINNING—The Registrar, College of Technology, Manchester, 1 (March 28)

ASSISTANT BACTERIOLOGIST (temporary), and LABORATORY ASSISTANT IN BACTERIOLOGICAL SECTION OF LABORATORIES (temporary) The Clerk to the Board, Metropolitan Water Board, New River House, Rosebery Avenue, London, E C 1 (endorsed "Assistant Bacteriologist" or "Laboratory Assistant", as the case may be) (March 31)

PRINCIPAL OF THE COUNTY MINING AND TECHNICAL SCHOOL, Nuneaton—The Organizer of Further Education, Council of Nuneaton (March 31)

PRINCIPAL OF THE LEIGH MUNICIPAL COLLEGE—The Secretary of the Local Higher Education Committee, Education Department Town Hall, Leigh, Lancs. (March 31)

SENIOR ASSISTANT IN THE COLLEGE LIBRARY—The Registrar, K College, Newcastle-upon-Tyne (March 31)

LECTURER IN GENETICS—The Secretary of University Court, University, Glasgow (April 7)

READER IN BOTANY AND HEAD OF THE BOTANY DEPARTMENT tenable in the Durham Division of the University—The Registrar, The University, 40 North Bailey, Durham (April 14)

PROFESSOR OF ECONOMICS—The Registrar, University College, Singleton Park, Swansea (April 21)

REGISTRAR—The Bursar (acting Registrar), The University, Lee (April 30)

SEDLIAN PROFESSORSHIP OF NATURAL PHILOSOPHY—The Registrar, The University, Oxford (June 2)

ASSISTANT IN THE DEPARTMENT OF AGRICULTURAL ECONOMICS under the Ministry of Agriculture Advisory Scheme—The Secretary and Bursar, Seale Hayne Agricultural College, Newton Abbot, Devon (March 31)

METALLURGIST (2) to undertake research in the welding of alloys—The Secretary, British Welding Research Association, 2 Epsingham Palace Gardens, London, S W 1

LECTURER IN SCIENCE (mainly BIOLOGY)—The Principal, Training College, Hereford

LECTURER (woman) to develop courses in GARDENING and RECREATION, and a LECTURER (part-time) with suitable qualifications experience to undertake with the students VOICE PRODUCTION, SPEECH TRAINING and SPEECH THERAPY—The Principal, St Mary's College, Cheltenham

TEACHER (full-time) OF MATHEMATICS—The Principal, Epsom Technical College, Queensway, Enfield, Middx

FORESTRY AND AGRICULTURE

IN previous issues of *Nature* (Sept. 25, 1943, p. 337, and Dec 2, 1944, p. 693), we have reviewed the proposals made by H.M. Forestry Commissioners and the Royal Forestry Societies of Scotland and England for the future administration and control of forestry in Great Britain. Matters were taken an important stage further on February 15, when Sir John Anderson made a statement in the House of Commons that for "securing more complete and more direct Ministerial and Parliamentary control, the better co-ordination of the development of agriculture and forestry, and the most efficient use of the woodlands which survive the War, and of further land available for afforestation", it was best to "enlarge the sphere of the Ministry of Agriculture and Fisheries and the Secretary of State for Scotland, so that these Ministers may become jointly responsible for forestry policy and for supervising the measures for its execution" This decision—reached, it is reported, after prolonged consideration of various possible alternatives—should occasion no great surprise, and should be admitted to come as near as it is possible to come to reconciling the divergent views expressed on the subject. Details are not yet available, but it was definitely stated that under this arrangement, "the Forestry Commission will be retained as a single continuing expert body responsible directly to Ministers for advice on forest policy and for carrying out operations including training, research and forest holding"

There has been general agreement among those interested that the existing position was no longer satisfactory, however well it may have been suited to the conditions prevailing when the Commission was set up in 1919. Critics have reiterated their view that there should be direct Ministerial and Parliamentary control in place of the peculiar position, only paralleled to some extent by such bodies as the Ecclesiastical Commission, of being included in no department of Government and controlled only in financial matters by the Treasury They have also expressed dissatisfaction with the composition of the Commission and the method of appointment to it It is always easier to point out what is believed to be wrong with an organization than to provide a certain remedy, and though the various proposals run on fairly similar lines, it cannot be said that there is unanimity as to what would at this stage constitute the best composition of a revised Forestry Commission and how appointments should be made to it It will be noted that there is fairly general agreement, however, that in one form or another, a commission does provide the best machinery for carrying out the forestry work required to be done in Great Britain during the post-war period.

Taking first this question of Ministerial control, it will be remembered that the Commission's own proposal (Cmd. 6447, par. 55) was that if, despite its recommendations, Parliament should wish it to be placed under the control of a Minister, that Minister should be the Lord President of the Council, perhaps

working through a committee for forestry including the Secretary of State for Scotland, the Minister of Agriculture and the chairman of the Commission. The Royal Scottish and Royal English Forestry Societies made the same recommendation, but they set out their reasons at some length (Report on Post-war Forestry, 1944, p. 23). To the layman, it would seem obvious that if it is advisable to include forestry in an existing Ministry, it should go with the closely related field of agriculture, and he would probably find it difficult to imagine why both the Commission and its critics should wish forestry to be included among the bodies under the control of the Lord President, which include the three important research bodies, the Medical Research Council, Agricultural Research Council and Department of Scientific and Industrial Research. What is it, then, that prompts the forester to look for some alternative to such linkage at the Ministerial level with agriculture? The answer lies primarily in his belief that there is a real risk that a Ministry of Agriculture might not accord to forestry that share of interest, staff and total available resources to which forestry considers itself entitled, that, in the terms of a much repeated quotation, agriculture might in fact treat forestry as its handmaid, taking moreover an out-of-date view of the proper relations between mistress and handmaid. If then the further question is put—What grounds has the forester for this mistrust?—reference might be made to the history of the relationship between the two forms of land use in certain parts of the British Empire, where forestry, when it was in competition with agriculture, appears to have had a difficult struggle to obtain a full hearing of its case and adequate recognition. Some of these points do indeed appear to support the argument, but clearly much depends on the setting, and it is easy—again ignoring the setting—to find illustrations working in the opposite sense, for example, the ultimately successful demand of the United States Forest Service early in its history to be included in the Department of Agriculture, and the strong opposition more recently to any proposal to break up this administrative arrangement. "The situation seems to call for careful consideration and, if necessary, the provision of some such safeguard as expressly earmarking funds for forestry. In view of the known interest in forestry of the Ministers who are at present responsible for agriculture in Britain, foresters need have few fears, but both appointments are political and the incumbents subject to change."

There was, moreover, thought to be a constitutional consequence of placing forestry in the same hands as agriculture, which British foresters generally deemed highly undesirable, namely, a splitting up of the existing single organization for Great Britain as a whole into two parts, one for Scotland under the Secretary of State for Scotland, and the other for England and Wales under the Minister of Agriculture and Fisheries. H.M. Commissioners are emphatic on the point (Cmd. 6447, par. 533), and so are the two Forestry Societies, though they consider the difficulty could be got over (cf. their Report, p. 23). Unity is

considered necessary to "ensure the high standard and *esprit de corps* expected of the Forest Service, adequate services for research, education and information, and a strong front to carry out an agreed national policy." It will be noted that this need arises from the fact that in Britain, even after the considerable expansion contemplated, forestry will still remain as a relatively small item on the national programme. Subdivision would mean further loss of strength, and the two services would each, in several aspects of their work, be too small for efficiency with economy. Obviously there must be a large measure of decentralization, permitting matters which are purely Scottish concern being dealt with in Scotland but no significant change from the present position will be required to ensure this. There will be dissatisfaction in Wales if special provision is not included to ensure the fullest consideration of Welsh interests, particularly as Wales will certainly be called on to provide a large proportion of the land required for afforestation. The existing consultative committees have been found to be too exclusively consultative, too lacking in power to press the views, to be acceptable.

It will be noted with approval that the Government has taken into account the need of the better coordination of agriculture and forestry. This is in keeping with the times, for this need is becoming more and more apparent to thinking men in both professions as well as to those responsible for general administration. The Forestry Commission has often been charged with disregarding it when acquiring land for State afforestation. It is of even greater importance in the case of privately owned woodlands, which must almost always be handled as an integral part of a mixed estate—woodland, arable and pasture, having their appropriate balanced parts to play in the general rural economy.

The statement made in the House of Commons also indicates that although we shall continue to have a Forestry Commission appointed by the Crown, its composition will be fundamentally altered by dropping the practice which has grown up of appointing representatives of each of the three chief political parties—one of the Commissioners had to be a member of the House of Commons to act as spokesman.

Men of science will note the specific mention of research as remaining under the control of the Forestry Commission, and perhaps wonder why it is not proposed to bring it under the Agricultural Research Council, as this would seem to be a logical step if the Ministry of Agriculture is to become responsible for forestry. A further announcement will be looked for with interest, as there have been numerous charges of inadequate attention to research in the past, but it may be noted that it would be quite possible for the necessary work to be shared between the Agricultural Research Council and the Ministry. The Ministry of Agriculture already has its own research stations for special problems, particularly those of a highly technological nature, and there are strong reasons why the Forestry Commission should in any event continue research of this type on

a wider scale than hitherto. Research of a more fundamental nature, which it has been the practice to 'farm out' to universities and other institutions wherever the best facilities were considered to exist for handling the individual problems, could perhaps more appropriately be taken over by the Agricultural Research Council, suitably enlarged by inclusion of persons with expert knowledge of the scientific aspects of forestry. There is a vast field for research into primary forest soils, tree physiology, and forest ecology in the widest sense, that has hitherto been much neglected. A variety of reasons for this neglect has been adduced, including experimental difficulties, lack of realization of the need for research, and lack of appreciation of the practical importance of the work. The essential requirement now is to remedy this, whatever is decided to be the best administrative arrangement to that end.

The accomplishments of the Forestry Commission during the first twenty-five years of its existence are reviewed in an article by Prof. E. P. Stebbing appearing in this issue (p. 317). If not a few matters are found for criticism, the reasons are often to be traced to the conditions under which the work has had to be done. It is indisputable that a great deal of valuable work has been accomplished during this quarter of a century, the completion of which would in any event have been a very appropriate time to take stock of the position reached. The initial difficulties involved in launching forestry as a new State activity have been successfully met. The nation's requirements can now be re-assessed and plans laid for a further period on the long-term views essential to sound forestry. In particular, we should now leave behind us the over-emphasis that has been laid on the afforestation aspects, give more attention to tending and management, and to preparing for the utilization problems that will shortly be upon us as the large acreages of plantation come into production. But the most significant feature of development to be anticipated in the draft legislation we are promised shortly is the proposed extension of the State's direct interest in some two million acres of privately owned forest. The Commissioners will need much imagination, tact and skill if at the end of the second twenty-five years they are to record as much progress in this field as they can record for their afforestation work since 1919. We believe this to be possible, and we certainly wish them every success in their task.

THE ROYAL SOCIETY, 1660-1940

The Royal Society, 1660-1940

A History of its Administration under its Charters
By Sir Henry Lyons. Pp. x+354. (Cambridge: At the University Press, 1944.) 25s. net

AFTER Sir Henry Lyons had finished his work on the fourth edition of the "Record of the Royal Society", he wrote in June 1940 to the present reviewer: "I have learned that what is badly needed is a new 'History', for, as you know, Weld's ends at 1830. Greatly daring I started on this about 2½ years ago and have got my first rough draft of half

of it in shape already. Now that I have got most of my facts collected and checked I see my way more clearly.", and again, in November 1941, "The further I get with it the less satisfied I feel". The subject tempts one to fling a wide net, but I have tried to keep to the story of how the Councils and the Fellows carried out their trust as laid down in the Charters, and with what degree of success." Notwithstanding the dislocations and discomforts of war-time aggravated by growing illness, he steadfastly completed that task, and lived to see his text in print but not to see it published. In the book, he says that he regards it as the introduction to a second volume which must be left for another hand to write a century or two hence—a remark which well illustrates the sense of continuity that permeates his work, and indeed, every fellow of the Royal Society should, with like diffidence, be a 'student of perpetuity'.

After a note by Sir Henry Dale, president of the Royal Society, and the author's introduction, the seven chapters of the book flow in chronological order from the sixteen-forties to 1940 (with repetitions wherever the author has not let system stand in the way of narrative needs), so as to bring out well-marked successive changes in the Society's life. Appendixes give a full translation of the second Charter (1663) into English, and statistical data, and there is a full index of names and subjects.

Throughout the book the author repeatedly insists—and produces evidence for it—that a scientific society can be run only by scientific men. The Charter of 1663 had expressed the lofty vision and purpose of the scientific founders and their wise lay supporters, but their momentum waned with the century, and during the seventeen-hundreds and later, the growing proportion of non-scientific fellows exercised, as the author shows, "a restraining influence on the Society's activity and hindered its steady growth as a scientific institution, after 1820 the control of the Society passed into the hands of men of science with the result that it quickly became what its founders had originally intended it to be, an institution devoted wholly to the advancement of scientific knowledge".

As would be expected from Sir Henry Lyons—a fellow of the Society for thirty-eight years and its treasurer for ten—the evidence which he presents is never guesswork; he always goes to original sources; much is from documents not hitherto used for publication, and, wherever he can, he adds quantitative data. Thus, not only is the book full of interesting facts about persons, but also it discusses such matters as lengths of tenure of office, the number of meetings of Council held in different years, the attendances at them, the representation on them of different occupations, scientific and other, their administrative and legislative acts and controversies, and the finances of the Society as far back as records go.

The graph on p. 344 plots the number of fellows for each quinquennium from 1663 until 1940, and is interesting. A few years after the foundation there were some 215 fellows, about a quarter of them scientific, but by the sixteen-nineties there were only 115, the nadir in numbers. The ensuing rise went on for a hundred and fifty years, and in the early eighteen-forties the fellowship touched its numerical peak, 766. But now began to be felt the reformation of control and administration which the author calls "The Scientific Revolt, 1820-1860", and, new elections of laymen having ceased, the total

number thenceforth fell, and so steadied down to about four hundred and sixty fellows and about forty foreign members, near which it has stayed for the past half-century.

Any serious work of history which scrupulously sets forth the evidence for its own inferences is, to some types of reader, dull. These types will be little attracted by this book, but it is not for them that Lyons wrote it. A scientific man and a careful historian, he wrote for his fellows, and perhaps above all for those who have or might have some part in the conduct of the Royal Society. There is none of such persons who should leave this work unread, it will teach them much of practical value. One of the many lessons implicit in it is that lively administration is essential to the furtherance of science but yet must be kept subservient to it. The Society has long learnt this, but it is sometimes forgotten by other planners, in their enthusiasm for logic and systems, that the best men of science are each *sur generis*, not units for regimentation, but beings for whose individual activities *qua* scientists the organization of society must elastically provide.

There is also another kind of reader who would well profit from some study of this book—namely, the general historian. For in the long run of history, thought proves more potent than engines, and the phases of the Royal Society in the past three centuries have partly reflected, but partly originated, deep changes of general thought in the nation at large, and beyond, and, without doubt, the recognition and tracing of these correlations enlightens real history.

J. I. O. MASSON

THREE MEN OF SCIENCE

Famous American Men of Science

By J. G. Crowther. Vol. 2. Thomas Alva Edison; Josiah Willard Gibbs (Pelican Books, A 105) Pp. 160. (Harmondsworth and New York. Penguin Books, Ltd., 1944.) 9d.

S. Z. Ferranti

(Science in Britain Series. Published for the British Council.) By L. Randell. Pp. vi+30+4 plates. (London. Longmans, Green and Co., Ltd., 1943) 1s net.

IT would be difficult to select two men of science who by ancestry, upbringing, development and achievement differed more widely than Thomas Alva Edison (1847–1931) and Josiah Willard Gibbs (1839–1903), whose careers are described in Mr J. G. Crowther's book. Of Dutch descent, Edison's forbears were physically strong, long-lived and commercial, while Gibbs came of British stock, less robust and devoted to academical studies. Of intensely practical habit of mind, Edison was given to inventing as much as Gibbs was to abstract reasoning. When during the Civil War of 1861–65 Gibbs was studying and lecturing in the seclusion of Yale, Edison, a mere boy, was selling and publishing the first newspaper printed on a train and beginning his career in telegraphy. Gibbs inherited ample means for his needs, Edison had to make his own fortune. Edison owed nothing to teachers, Gibbs everything, and from the age of twenty-six to twenty-nine was able to study under famous physicists in Europe, but both made notable contributions to scientific and industrial progress.

To understand Gibbs's work, however, a thorough grounding in scientific principles is necessary, but everyone can appreciate Edison's hundreds of inventions, his lamps, dynamos, phonographs, etc. It is impossible to compare the two men, they were as different in temperament, character and mode of living as Cavendish and Trevithick. Mr Crowther rates Edison as "the greatest inventor recorded in history", but that and other statements only provoke one to thought, just like the story of the members of a British scientific society who, balloting for the greatest twenty scientific men since the Renaissance, chose in order, Newton, Darwin, Faraday, Einstein and Gibbs. One of Gibbs's contemporaries who worked at thermodynamics was John Macfarlane Gray (1832–1908), but Gray was not, as Mr Crowther says, "chief engineer of the British Royal Navy", his official position was examiner of engineers for the Board of Trade.

In the same category of men of genius can be placed Sebastian Ziani de Ferranti, who is the subject of Mr L. Randell's little pamphlet, one of a series dealing with British men of science and scientific institutions being published in English, Spanish and Portuguese for the British Council. Ferranti was born in Liverpool in 1864, and by the age of twenty was a manufacturer of dynamos, meters, transformers, etc. His early years were as astonishing as those of Edison, and to him more than to any other single individual is due the conception of the central super-power station generating electricity at high voltage, and its distribution over wide areas. He died in 1930, honoured throughout the engineering profession.

U.S. ANIMAL INDUSTRY

Introductory Animal Husbandry

By Prof. Arthur L. Anderson. Pp. xi+777. (New York. The Macmillan Company, 1943.) 20s net.

BETWEEN Britain and the United States there are many differences in situation, and there is a corresponding diversity of outlook. Such differences are particularly marked in their respective livestock industries and are historical and geographical in origin. Many of the American breeds came from the British Isles, but, in the place of stock in agriculture, in marketing arrangements, in food habits, there are great contrasts. The Englishman likes his breakfast bacon and Sunday joint, the American prefers porter-house steak, frankfurters, and (in moderation) 'Spam'. Britain is not self-sufficient in meat or animal feeding stuffs, livestock are an essential part of an intensive mixed agriculture, droughts are very inconsiderable affairs. In America there are well-defined regions—cotton, wheat and corn belts, distances are important because dairying must be within a few hours' journey of population centres, the opening up of the interior by railways led to the packing-house system.

Prof. Anderson, in the scope of his book, has been guided by a survey by his publishers. It is designed as a text-book for students beginning a college course and for reference in vocational training. Sections of approximately equal length deal with beef cattle, milking cattle, sheep, pigs, and horses and mules. References are given only to readily accessible American publications.

Animal husbandry is defined as the breeding, feed-

ing and management of domestic animals, in introducing the subject, the author is less concerned with the animals than with their position in domestic trade and the economics of their production. Thus, of ten chapters dealing with beef cattle, one is devoted to feeding and management and one to breeding; the remainder concern show-points and classes, marketing, meat grading, by-products and consumption, together with a brief historical introduction. Extensive use is made of statistics from packing-houses, U.S. Department of Agriculture surveys and the like, dealing with such matters as seasonal fluctuations in market receipts and prices, percentage losses through injury in shipment by rail or road, average live-weights at slaughter-houses, milk distribution costs, and so on. A list of slaughter-house by-products and their disposition extends to incense and oriental medicine. In contrast, no details are given of the composition of feeding stuffs, nor is there any mention of the ruminant stomach (except as tripe). Similarly, though wastage in dairy cattle is very high, there is no discussion of the causes. A curious omission is the absence of any reference to machine milking.

Housing, feeding and breeding are dealt with very briefly, a survey is given of usual practices and of economic aspects such as the price equivalents of corn and butterfat. Certain remarks on management have a very practical ring and a more than local application. Two may be quoted here: "To top the market with beef steers is the fond hope of many cattle producers. It is not always related to the most profit from the feeding enterprise", and again, of sheep: "Not all pure-bred flocks exhibit sheep at shows and expositions, but fitting for sale is essential for selling to the best advantage. Likewise a pure-bred flock manager should have salesmanship ability. The showing of a flock at the livestock shows is a form of advertising."

Prof. Anderson has aimed at the presentation of facts and the avoidance of matters of controversy. He has made much use of the findings of technical investigations. Some three hundred illustrations portray for the most part ideal breed types, industrial processes and price and population trends.

FUNDAMENTALS OF ASTRONOMY

From Atoms to Stars

By Dr. Martin Davidson. Pp. 188. (London, New York and Melbourne: Hutchinson's Scientific and Technical Publications, 1944.) 15s. net.

BOOKS written with the view of meeting the enlarged interest in astronomy manifested by the ordinary individual in recent years have not been lacking on either side of the Atlantic. One of the latest, for British readers, bears the comprehensive, if somewhat inconsequent, title "From Atoms to Stars" and is from the pen of Dr. Martin Davidson, prominent among British astronomers for his wide theoretical knowledge of the subject. To quote from the preface, it is "intended to provide a general outline of the most up-to-date knowledge of the heavenly bodies and also to show the methods employed by the astronomer to derive their distances, sizes, masses, temperatures, etc."

It is the latter aim which gives to the book its distinctive character. As if to warrant the title,

Chapter I is devoted to an account of the structure of the atom, according to present views, touching upon ionization, radioactivity, transmutation and allied phenomena. The reader is thus prepared for a description, later in the book, of the sub-atomic processes by which the enormous output of radiant energy continuously emitted by the sun and the stars has been maintained for thousands of millions of years.

The succeeding chapters follow the general plan adopted in books of this type. They deal in turn with the sun, the earth and the moon and phenomena relating to these bodies, next with the other members of the planetary system, including meteors and comets, and then five chapters are devoted to the stellar universe at large, in all its diversity of objects. Positional astronomy and star-configuration find no place in the book.

Each chapter contains, in addition to ample descriptive and explanatory matter, much interesting detail of a kind not commonly found in non-technical books, while in a few cases a short bibliography is appended for the information of readers who may wish to enter more deeply into the subject.

Dr. Davidson's mathematical bent finds an outlet in the fulfilment of his promise to show how astronomers tackle their theoretical problems. Many worked examples are incorporated in the text, most of them being in reality quite elementary, and some, perhaps, given at unnecessary length. This plan makes it difficult for readers to avoid the arithmetic even though they may wish merely to know the methods.

The final chapter contains a summary of various theories of the origin of the sun's planetary system, beginning with those of Kant and Laplace and concluding with several speculations of very recent date. The author is of opinion that none is really satisfactory.

A few typographical mistakes have slipped through the "proof" stage—chiefly transposition of digits, of which the outstanding example is on page 132, where the value of a radian in degrees is stated to be $\pi/180$ instead of $180/\pi$. On pages 152, 153 "J. C. Adams" is a slip for Walter S. Adams. The director of Mount Wilson Observatory, California, is of course not to be confused with the ever-famous Prof. J. C. Adams of Cambridge, who first demonstrated the existence of the planet Neptune, which was discovered later. It is surprising, also, to find Dr. Davidson giving renewed currency to the idea that the double high tides experienced at certain places—for example, at Southampton—are due to the successional arrival of the tidal wave by two different routes. This superficially plausible explanation has been shown by such authorities as Lord Kelvin and Sir George Darwin to be fallacious.

The book is illustrated with excellent photographs and many instructive diagrams. The style is pleasantly colloquial, though a feeling sometimes arises that the author, in compressing his material, is unconsciously stepping above the standard envisaged in his preface, and is taking for granted rather more astronomical knowledge than the average reader would be likely to possess. Nevertheless, to readers with ordinary scientific outlook, "From Atoms to Stars" can be heartily recommended as an authoritative, up-to-date outline of astronomy's wonderful achievements in the exploration of the infinities both of space and time.

W. M. WITCHELL.

The Chemical Testing of Plant Nutrient Solutions
By G. S. Fawcett and Dr R. H. Stoughton Pp. 86
(Salisbury The Tintometer, Ltd, 1944) 8s. 6d

THE routine testing of plant nutrient solutions is undoubtedly an important part of most investigations on the soilless growth of plants, and the genuine investigator must therefore be competent to carry out the necessary chemical operations. In this book, which is essentially a set of directions for carrying out the tests, the authors have succeeded in reducing the operations to as simple a form as possible, to give speed in analysis but yet to retain an accuracy sufficient for the purpose. This result has been achieved by employing, in all cases, colorimetric or nephelometric methods which must be used in conjunction with the 'All-Purpose Lovibond Comparator' and special standard colour and turbidity disks and comparator tubes. The chemical methods have been selected from text-books and the literature, and have been adjusted and critically tested under the conditions existing in plant nutrient solutions. They provide for the estimation of the major plant nutrients and the minor and trace elements manganese, iron, boron, copper and zinc. In some cases the methods are tentative and the authors hope to improve these. As with the simplification of many chemical methods, the applicability is restricted, in this case to plant nutrient solutions only, and the authors are emphatic that all details be adhered to closely. If this advice is followed, the novice can carry out some of the tests by himself, but others involve highly corrosive chemicals, and although ample detail and space is devoted in the early part of the book to the very elementary operations of handling chemical glassware and reagents, those who are inexperienced in chemical technique should, in the opinion of the reviewer, receive a short preliminary training.

This book, together with the specially designed apparatus, should prove a great help to experimenters in the soilless cultivation of plants. R. G. WARREN

Symposium sobre Raios Cósmicos, Rio de Janeiro, Agosto 4-8, 1941

Pp 180+19 plates (Rio de Janeiro Academia Brasileira de Ciências, 1943)

IN this volume are reprinted, in English and French, the papers given at a symposium on cosmic rays held in August 1941 at Rio de Janeiro, under the auspices of the Brazilian Academy of Sciences, on the occasion of the visit of a group of American physicists led by Prof. A. H. Compton. The scope of the conference is indicated by the following titles selected from some twenty papers: (1) "On the Fluctuations of Cosmic Rays", by A. H. Compton, a discussion of the sidereal time variation of cosmic rays; (2) "On the Latitude Effect of Cosmic Rays", by B. Gross; (3) "Cosmic Ray Studies in the Andes of Southern Peru", by N. Hilberry and A. H. Hilberry. This paper describes the determination of the variation in the frequency of extensive showers with altitude, up to 5,850 m above sea-level, for two different counter arrays, and affords an interesting proof that most extensive air showers are initiated by high-energy electrons; (4) "Cloud Chamber Photographs at High Altitudes", by D. Hughes; (5) "The Latitude Effect for the Hard Component of Cosmic Rays and Evidence as to the Nature of the Primary Radiation", by W. P. Jesse; (6) "The Influence of a Solar Eclipse on the Cosmic Ray Intensity", by Y.

Monteux, G. Occhialini and M. D. Souza Santos. (7) "On the Ultra-Soft Component of Cosmic Radiation", by G. Occhialini and M. Schonberg; (8) "Showers of Penetrating Particles under 30 m of Clay", by P. A. Pompeia, M. D. Souza Santos and G. Wataghin; (9) "On the Production of Mesotrons at High Altitudes", by E. O. Wollan. This interesting paper gives the results of balloon flights to determine the multiple production of mesons as a function of altitude. No maximum is found up to a height corresponding to a pressure of 3 cm of mercury.

It is unfortunate that publication of this report has been so long delayed, for much of the original work presented at the conference has been published in the meantime. G. D. R.

Fitz-James O'Brien

A Literary Bohemian of the Eighteen-Fifties By Prof. Francis Wolle (University of Colorado Studies, Series B Studies in the Humanities, Vol. 2, No. 2) Pp. xi+309. (Boulder, Colo. University of Colorado, 1944) 2 dollars

IN this painstaking and amply documented study Mr. Wolle follows the fortunes of a young Irishman who arrived in New York in 1852 with nothing but his wit and ready pen for luggage, and, in the next ten years, poured out a flood of ephemeral literature, reflecting the many facets of contemporary society. Such a chameleon could not escape the mid-nineteenth century interest in scientific discoveries and pseudo-scientific speculation. In his short stories, which rival in horror those of Poe, figure an invisible monster, a glass eye, robot killers, disembodied organs which continue to function normally, a swiftly revolving ball which is impervious to the force of gravity ("How I Overcame My Gravity"), a telepathist and, in his best-known work, "The Diamond Lens", a microscopist. This miscreant, by means of cold-blooded murder, produces the perfect lens, only to discover his ideal woman in a drop of water. Unable to make contact with her, he is doomed to watch her fade as the water evaporates. He goes mad.

Unfortunately science, in the hands of an inept surgeon, was unable to save O'Brien from the result of a pistol shot in the left shoulder, which he got while fighting with a New York regiment during the Civil War. After much needless suffering, a resection of the joint was decided on, tetanus set in, and this gifted but irresponsible Bohemian died at the age of thirty-three. Whether he would ever have fulfilled the fitful promise of his early years seems doubtful, and one wonders if it was worth while so meticulously to disinter his literary remains. They have something of a charnel-house smell, and one can only wonder at the mediocrity of a literary society in which their author ranked with the best. PHYLLIS HARTNOLL

Studies on Immunisation

Second Series With Appendices dealing with Anti-typhoid Inoculation, Chemotherapy, and Statistical and other Operations of Induction. By Sir Almroth E. Wright (Researches from the Inoculation Department, St. Mary's Hospital, London, W.2, Vol. 4) Pp. vii+256 (London: William Heinemann (Medical Books), Ltd., 1944) 25s. net

THIS volume contains selections from the published works of Sir Almroth E. Wright and his collaborators. The subjects include vaccine therapy, prophylactic inoculation against pneumonia, and other aspects of the field of immunity.

THE FORESTRY COMMISSION

THE FIRST TWENTY-FIVE YEARS

By PROF. E. P. STEBBING
University of Edinburgh

AS a result of the restrictions on imports and the heavy fellings made in the woods in Great Britain during the War of 1914-18, a Forestry Subcommittee was set up to consider the question for the country as a whole, and its report, the Acland Report, was accepted by the Minister of Reconstruction and the Cabinet as a basis upon which to frame a Forestry Bill. This Bill was passed in 1919.

The idea underlying the framing of the Bill was the necessity of making provision, against a possible future war, for a three years supply of timber and pit wood in the country. The estimated area to furnish this amount was laid down as 1,770,000 acres. This area was to be planted in a period of eighty years at a total cost of £15,000,000. During the first ten years, for which the Bill provided, an area of 250,000 acres was to be planted at an estimated cost of £2,872,500.

The chief work, therefore, of this new State Department was to bring into being a State ownership of forest land and to afforest all suitable parts of these areas, to create, in fact, national forests, a type of ownership of woods which had never previously existed in Britain. For the so-called State forests, the Dean, New Forest, and so forth, were originally, and had come down to us solely as, the personal property of the Crown. This pioneer work of acquiring land, draining, clearing, fencing and raising the plants required in nurseries and having the requisite number ready each year for the estimated areas to be planted up was by no means so easy as had perhaps been anticipated by some of the most ardent adherents of the new departure. Further, the recruitment of the indispensable trained staff proved another difficulty. Under the Forestry Bill the Commission was to receive annual grants to cover its expenditure. In forestry, a type of work necessitating the longest views, since trees do not grow to maturity in the brief space of agricultural crops, a departmental budget based on stability is indispensable. The financial crises which supervened between 1920 and 1931 had their automatic effects on checking and upsetting the annual planting plans so rigidly laid down in the Acland Report, one of its chief failings, and consequently the activities of the new department. In this connexion and owing to the inexperience of the staff, unnecessary waste was inexorably incurred at these set-backs. Large numbers of plants were actually burnt in the great nurseries owing to the cutting down of the yearly planting programme, whereas there is no doubt that they could, with considerable advantage, if only in the interests of the taxpayer, have been offered at the cost of carriage to private owners of woods, as is so commonly done in Europe and, in fact, is at the present time being done in certain parts of the British Empire overseas.

In this connexion there was another serious drawback to the Acland Report, to which the Commission adhered so rigidly. The report was based almost solely on the annual planting of conifers. The valuable British broad-leaved species or hardwoods were almost entirely neglected. In fact, in parts of

Britain where poorly managed areas of coppice with standards were purchased with the estate acquired by the Commission, such was the conifer obsession that these areas after being cleared were planted with conifers, this often resulted in a heavy cleaning expenditure for a number of years to prevent the resultant coppice shoots—the natural tree flora of the locality—from smothering and killing the expensively raised and planted conifers.

It will be readily admitted that the new department had to show results, or it would have risked suppression at the hands of a lukewarm Government, House of Commons and public, and conifers are easier to raise and plant and grow more quickly than hardwoods. Moreover, the bulk of the land acquired by the Forestry Commission was conifer land.

The acquisition of the necessary land did not prove so easy. For one thing, the agricultural parts of an estate together with buildings and so forth had to be acquired, since a depreciation in values would result if only a specified portion of an estate were sold.

In the past twenty-five years the Commission has acquired approximately $1\frac{1}{2}$ million acres, of which half a million acres has been afforested and a quarter of a million acres remains to be planted. The rest of the land is either unproductive, above the present possible plantable elevation, and mountain tops, or land which is agricultural in its broadest sense and therefore does not fall within the province of the forester. These land areas now belonging to the State, that is, the public, are spread over 263 forests, of which 102 are in England, 39 in Wales and 122 in Scotland. It was foreseen that in these at present out-of-the-way-regions it would be necessary to make provision for accommodation for permanent forest workers. A programme was therefore prepared for the building of forest holdings, that is, houses each with an acre or two of land to produce vegetables and so forth, 1,500 of these holdings have been established during the period.

In England and Wales an area of 625,505 acres of land has been acquired, of which 464,178 acres is plantable land, the rest being described as agricultural holdings, nurseries, unplatable, etc. The areas planted were 276,898 acres of unafforested land and 49,102 acres of acquired woodland (the New Forest, Forest of Dean, etc., made over to the management of the Commission). The chief species used in the re-afforestation work and in planting in the acquired woodlands were Scots and Corsican pine, European and Japanese larch, Norway and Sitka spruce, Douglas fir (very popular in the early years of the Commission), oak and beech. In Scotland the total area acquired has amounted to 627,000 acres, of which 316,000 acres is plantable. The area planted has amounted to 163,000 acres, the species used being Norway and Sitka spruce, about 53 per cent, Scots and Corsican pines, about 26 per cent; European and Japanese larches, about 11 per cent, others, 10 per cent.

On the subject of private forestry, the Commission states that grants given for planting in private woodlands have been made in respect of 145,000 acres, the grant being £2-£4 per acre. Land owners, while gladly acknowledging this assistance, complained that since practical assistance by the Commission was not available, the planting-rate on estate woodlands was not much more than 6,000 acres a year, as compared with nearly double in the early years of the present century, although after

the heavy war fellings during 1914-18 the planting-rate should have been greatly accelerated. In 1914 some 97 per cent of the woods in Great Britain, amounting to $2\frac{1}{2}$ million acres, were privately owned. The Commissioners claim, nevertheless, that advice on many aspects of forestry has been given to private owners. But it must be admitted that the private owners had a strong case when they maintained, first, that the new and very young State forest staff had a full-time job, increasing with the passing years, and that little time was therefore available for advice to the private owner. More than this was, however, involved, the training and experience of the staff, with no long tradition and no precedents behind them, were not always adequate to enable them to advise in the management of estate woodlands, especially the smaller ones, which presented a whole set of quite different and often very complex problems.

An interesting side-line of the work of the Commission, but a natural development, as it turns out, is the creation of three national parks on the State-owned forest land, and two more are to follow. The controversies which have taken place over the question of the afforestation of beauty spots were probably almost inevitable in a country such as Britain, with a population which knew nothing about forestry or its objectives and had lost all forest sense. That the young department may have blundered in some cases is scarcely to be wondered at. But the ignorance of the public on the subject was equally apparent.

Towards the end of the period here dealt with, the Commissioners have prepared two White Papers on post-war forestry. The first of these has had a first reading in the House of Commons.

The present Commissioners were appointed by the King, and their average length of service is now ten years. The first chairman and the man who may be said to have made the Commission was the late Lord Lovat, 1919-27, followed by Lord Clinton, 1927-29, Sir John Stirling Maxwell, 1929-32, and then Sir Roy L. Robinson, 1932 to date. Mr Robinson was the technical commissioner to Lord Lovat and remained in the Commission in this capacity until his appointment as chairman. In the first few years, the Commission consisted chiefly of landed proprietors—to this reason perhaps may be attributed the failure to start replanting all the cut-over areas of 1914-18, since they might have been accused of helping themselves. On the other hand, it is conceded that it was due to Lord Lovat as chairman that the Commission survived the financial crises which supervened so quickly after its birth. Latterly, the Commission has had a far greater political and House of Commons flavour in its composition.

A point often raised during the past twenty-five years was the irresponsibility of Ministers and the Cabinet for the progress of forestry in Great Britain. The Forestry Commission was represented by a Commissioner, a member of the House of Commons, who acted as its spokesman. Many considered that this was far from effective, that it placed the afforestation programme of the country, a purely public matter, in constant jeopardy, that, in fact, either the business was sufficiently important to deserve the attention of, and responsibility for, a Minister of State, or the Government should give its reason for leaving the matter in the hands of a more or less autocratic authority control led solely by the Treasury. This may be said to have been the

practice at the close of the twenty-five years work. In the House of Commons on February 15 it was announced that the Minister for Agriculture and the Secretary of State for Scotland will in future be jointly responsible for forestry, the Forestry Commission being retained as an advisory body with executive functions (see p. 311).

One of the present troubles the staff of the Forestry Commission have had to deal with has been fire damage, always a serious danger with large areas of young conifers. Considerable research work into certain problems in connexion with little-known aspects of the work facing them was undertaken in the early years, for example, investigations into seed qualities and the best regions to obtain the seed from, since so many of the species being used in the new work were exotics, nursery investigations on methods of sowing, soils, rate of growth and so forth, manuring, diseases in the nursery, both fungal and insect attacks, etc., including climatic factors, brought forth excellent results in some cases, as also the studies made of the soil flora in different regions and growth statistics. More spectacular and easier to understand were the experiments carried out with the object of learning how to plant areas of peat land often of some depth, of which a not inconsiderable proportion of the land acquired by the Commission consisted. Sufficient here to say that great success was attained in some regions by the employment of tractor ploughing. The great increase in mechanization in connexion with farm implements of all types enabled the Commission to devise, and the makers to construct, a tractor plough of such power that areas of deep peat, hitherto beyond the ability of man to cultivate in any way, are now turned up into deep furrows and ridges, enabling drainage to be given to the area while the young trees are planted on the ridges. Continually increasing areas of such lands are being afforested, and it is a sight well worth visiting, whether from a scientific or popular point of view.

Other experiences likely to be of considerable interest to the scientific man are the investigations which have had to be taken up at short notice in connexion with pests. In the early years, great hopes were placed on the Douglas fir, but a *Chermes* appeared on it and threatened young plantations wholesale. The *Hylobius* weevil was a well-known pest, but although in Prussia chiefly confined to Scots pine, the extended work of the Commission showed that the weevil would attack several of the exotic coniferous species being used. The interest of this work lies in what is becoming a recognized factor in planting work, whether agricultural or forestry, that a large and sudden extension on a countryside will invariably be accompanied by an increase in local pests, and not uncommonly the appearance of new ones.

Looking back over the past twenty-five years, it may be said that the Forestry Commission and its officers are to be congratulated on the work which has been accomplished in spite of often difficult obstacles. The public now participate as owners in a forestry estate which with adequate support, both financial and otherwise, will form a great asset to Great Britain, always provided that the growth of the hardwoods in their respective regions is not neglected, for some of them produce the finest timber of the temperate zone, while their beauty has made English scenery as enchanting as any the world can show.

NICOTINAMIDE METHOCHLORIDE AND ITS FLUORESCENT DERIVATIVES

By DR. P. ELLINGER

Lister Institute of Preventive Medicine, London

THE methylation of pyridine in the animal body was observed by His¹. When he showed that pyridine was converted to N-methyl pyridinium hydroxide and when Ackermann² found that ingested nicotinic acid was partly eliminated as trigonelline, these observations were at that time mainly of theoretical interest. They became of practical value, however, when nicotinamide was shown to be a constituent of the coenzymes I and II by Warburg and Christian³, Warburg, Christian and Griese⁴, and v. Euler, Albers and Schlenk⁵, and their significance became obvious when Knight⁶ demonstrated the importance of nicotinic acid as a growth factor in bacteria, and Elvehjem, Madden, Strong and Woodley⁷ showed the curative effect of nicotinic acid in canine black tongue and suggested its identity with Goldberger's PP factor, this fact was verified by numerous investigators. It was of considerable interest, therefore, when Najjar and Wood⁸ published their discovery that a whitish blue fluorescent substance was present in the urine of normal subjects and was increased in amount after the ingestion of nicotinamide and other related compounds.

The fluorescent material was demonstrated when a 'Decalso' adsorbate of urine was eluted with potassium chloride solution and the solution was made alkaline and extracted with butanol. The butanol extract showed fluorescence when exposed to the light of a mercury vapour bulb filtered through a Wood glass filter. In an attempt to identify the substance a large number of pyridine derivatives were examined, but none of them revealed the characteristic fluorescence when tested under similar conditions. The fluorescence spectrum in butanol was determined, a number of observations were made upon the stability and solubility of the fluorescent substance in butanol and a rough method of assay was devised by matching the fluorescence intensity of the butanol extract against that of a standard solution of quinine sulphate. Somewhat later, Najjar and Holt⁹ described a second substance that possessed a violet-blue fluorescence which became visible when the potassium chloride eluate of a urinary 'Decalso' adsorbate was extracted with butanol without adding alkali. This substance was called F_1 by the authors, while the substance observed after alkalinization was called F_2 .

The pigment F_1 was found in the urines of patients in the acute stages of pellagra and of black tongue dogs in which F_2 was more or less reduced. A number of theories were put forward about the nature of F_1 and F_2 and their function, and it was suggested that F_1 might be responsible for the photosensitivity of pellagrins. The fluorescence of F_1 was also characterized by its emission band. The administration of nicotinic acid to pellagrins and black tongue dogs caused a prompt reduction of F_1 and reappearance of F_2 ^{10,11}. The nature of F_1 is still unknown. A number of pyridine and pyrazine derivatives were tested for their power to increase F_2 , but nicotinic acid, nicotinamide and nikethamide alone were found to be active. These compounds were also known to be active in the cure of pellagra.

A violet fluorescent substance was reported by Singal and Sydenstricker¹² in the urine after ingestion of pyridoxine. The pigment is said to be present in the neutral butanol extract of a potassium chloride eluate of a urine adsorbate on 'Decalso'. Ellinger and Coulson¹³ were unable to confirm this observation, but Huff and Perlzweig^{14,15} succeeded in isolating the fluorescent material and identified it as 4-pyridoxic acid.

An attempt was made to use the elimination of F_2 by animals and man for the estimation of nicotinamide and related compounds in foodstuffs at the suggestion of Dr B. S. Platt. For this purpose dogs, ferrets and human volunteers were calibrated with nicotinamide and a preliminary method giving comparable but not absolute values was devised for the quantitative assay of F_2 in urine^{16,17}.

In order to develop an assay method providing absolute results, it was necessary to elucidate the chemical nature of F_2 . Attempts were made, therefore, to concentrate and purify the fluorescent pigment contained in the butanol or isobutanol extracts¹⁸. The purification was carried out with the aid of the ultra-violet absorption spectrum. The absorption spectrum, the fluorescence spectrum and the behaviour of the substance towards reducing agents, alkali and acid, were so similar to those of thiochrome that F_2 was thought to be a mixture of thiochrome and a whitish fluorescent substance. Differences in the adsorption on 'Decalso' of F_2 and thiochrome at different pH's later proved that this conclusion was incorrect¹⁹.

Two papers on the chemical nature of F_2 were published simultaneously by Najjar, Scott and Holt²⁰, and by Huff and Perlzweig²¹. The former authors concentrated and purified F_2 and examined the properties of the concentrate. They observed its fluorescence in presence of alkali and acid, and recorded its stability towards oxidation; they observed the irreversible formation of a violet fluorescence after treatment with alkali and potassium ferricyanide, of a yellow pigment with green fluorescence after treatment with alkali and acetone, and of a non-fluorescent orange-red pigment after the addition of sulphanilic acid. These workers proved that F_2 is a pyridine compound by producing a positive cyanogen bromide test after alkaline hydrolysis. They realized that there were similarities between F_2 and the reduction products of N-methyl nicotinamide, but were unable to identify F_2 with one of these products on account of certain discrepancies.

Huff and Perlzweig²¹ showed that animal species which were known to methylate ingested nicotinic acid eliminate increased amounts of F_2 after the ingestion of nicotinamide, while rabbits, which are unable to perform this methylation, do not eliminate F_2 after nicotinamide dosage. They claimed to have established the identity of F_2 with synthetic N-methyl-nicotinamide on the basis of the identity of the melting points and mixed melting point of the respective picrates. They concluded that " F_2 thus appears to be a N-methyl nicotinamide or a labile precursor which yields this compound in the course of isolation". Somewhat later²², they stated "A crystalline substance was isolated from human urine after dosage with nicotinamide. From comparison with synthesised N-methyl-nicotinamide chloride in regard to content of nitrogen, chloride and nicotinic acid, and in regard to the absorption spectra, fluorescence and the melting point of the picrate the two

substances were found to be identical. This establishes the identity of the fluorescent substance, F_2 , previously described by Najjar, Holt, and their collaborators¹⁷. They proved that most of the trigonelline found by earlier methods in animal urine after nicotinamide ingestion was in reality nicotinamide methochloride—a fact already made probable by Sarrett²³.

Ellinger and Coulson^{19,24} also attempted to determine the chemical nature of F_2 , and examined isobutanol extracts that had been evaporated at 60°. The material revealed the presence of at least five different fluorescent substances which could be separated chromatographically or by fractionated sublimation. When the concentration and purification of natural F_2 or of the fluorescent derivative of synthetic nicotinamide methochloride was carried out at room temperature, however, chromatographic adsorption analysis revealed the presence of only two fluorescent compounds, which were called F_{2a} and F_{2b} .

Up to that time, it was generally believed that F_2 was eliminated in the urine as a fluorescent pigment. This erroneous conclusion was responsible for much unnecessary work and gave rise to considerable confusion, which with certain workers still persists. Keresztesy²⁵, for example, still speaks of the fluorescent F_2 appearing in human urine. Ellinger and Coulson¹⁹ showed that when examined in the light of the 366 and 311 mμ mercury lines, neither the potassium chloride eluate of an adsorbate of urine on 'Decalco' nor that of an aqueous solution of nicotinamide methochloride is fluorescent, but that both become slightly fluorescent when made alkaline and that the fluorescence becomes more intense when the alkaline substance is extracted with isobutanol. Huff and Perlzweig²⁶ discriminated for the first time between the fluorescent F_2 and its non-fluorescent precursor in a paper published in 1944, in which they claim that their original investigation was concerned with the non-fluorescent precursor of F_2 and not as indicated in their earlier publications^{21,22} with the fluorescent derivative. The comparison by Ellinger and Coulson^{19,24} of a number of properties of the non-fluorescent precursor of F_2 and of synthetic nicotinamide methochloride, such as melting points of picrates and mercury iodides, absorption spectra, behaviour towards treatment with alkali and isobutanol, absorption and emission spectra of the fluorescent derivatives showed the complete identity of the two compounds. The only difference observed was that in the melting points of the aurates. It is to be noted, however, that aurates with different melting points and gold content were observed for trigonelline by Jahns²⁷, and, therefore, a difference of this kind cannot be accepted as indicating that the two compounds are different. A different gold content was observed, indeed, for the aurates of the natural precursor of F_2 and the synthetic nicotinamide methochloride, and three aurates could be obtained from the latter differing in colour, crystal structure and melting point (Ellinger²⁸).

The careful analysis of the behaviour of both the natural non-fluorescent precursor of F_2 and the non-fluorescent nicotinamide methochloride after treatment with alkali and isobutanol revealed the following facts. In aqueous solution, when examined in the beam of the 366 mμ and 311 mμ mercury lines, both substances are non-fluorescent. After the addition of alkali a weak whitish-blue fluorescence develops which can be extracted with isobutanol and increases

as much as 400 times in intensity when in isobutanol. The absorption spectra of the non-fluorescent precursor of F_2 and of nicotinamide methochloride show maxima at 264 mμ, recorded by Huff and Perlzweig²² for F_2 and nicotinamide methochloride. The absorption spectra of F_2 and of the synthetic nicotinamide methochloride derivative obtained after alkali and isobutanol treatment showed maxima at 358 mμ. The addition of alkali to the precursor of F_2 or synthetic nicotinamide methochloride in aqueous solution causes practically no change in light absorption.

These facts lead to the conclusion that alkalization causes a change in the nicotinamide molecule. By analogy with the findings of Hantzsch and Kalb²⁹ and of Decker and Kaufmann³⁰, a migration of the OH group from the pyridine N to one of the pyridine C atoms with simultaneous loss of one double bond in the pyridine nucleus and formation of carbinols was suggested. The low fluorescence intensity and the practically unchanged absorption spectrum in aqueous solution after alkalization showed that in water the equilibrium between the quaternary pyridinium base and the carbinols was in favour of the former, while the high fluorescence intensity and the almost complete change of adsorption spectrum in isobutanol indicates a reversed equilibrium in the latter solvents.

Adsorption on aluminum oxide of the purified F_2 as well as of the fluorescent derivative of nicotinamide methochloride and elution with isobutanol and methanol, respectively, revealed the presence in F_2 of two fluorescent compounds, F_{2a} and F_{2b} , each possessing different absorption and emission spectra. The form of their absorption spectra and the similarity with dihydro derivatives of nicotinamide described by Warburg and Christian³, Warburg, Christian and Giese⁴, and Karrer, Schwarzenbach, Benz and Solmsen³¹ lead to the conclusion that F_{2a} was probably the γ-carbinol, and F_{2b} an α-carbinol of N-methyl dihydronicotinamide. In the light usually employed, which is derived from a mercury vapour lamp filtered by Wood glass, the emission spectrum of F_2 is almost identical with that of F_{2b} , since the primary light consists mainly of the 366 mμ lines which are strongly absorbed by F_{2b} but very little by F_{2a} .

Perlzweig, Bernheim and Bernheim³² made the important observation that nicotinamide but not nicotinic acid is methylated *in vitro* by liver, but not by kidney, or muscle slices of rats. Usually, but not always, this methylation of nicotinamide is increased by addition of methionine or choline. The methylation process requires the presence of oxygen and intact living cells.

Further observations on the nature of F_2 were published by Najjar, White and Scott³³, and by Najjar and White^{34,35}. In the last two communications^{34,35}, Ellinger and Coulson's¹⁹ original observations that the metabolite of nicotinamide was non-fluorescent and became the fluorescent F_2 by treatment with alkali and isobutanol was confirmed, whereas in the earlier paper³³ no discrimination was made between F_2 and its non-fluorescent precursor. Najjar, White and Scott³³ describe the preparation of a purified F_2 concentrate as a waxy material from which crystals were obtained by treatment with ethyl acetate, water, or methanol. A number of properties of these crystals were described. The absorption maximum of the fluorescent F_2 is described as at 264 mμ, which corresponds to that found by Ellinger and Coulson¹⁹ for the aqueous non-fluorescent precursor, the maximum for the fluorescent F_2 iso-

butanol solution was found by Ellinger and Coulson to be at 358 m μ . Alkaline hydrolysis of the crystalline material afforded a product giving a cyanogen bromide reaction. Najjar and co-workers^{33,34,35} accept the conclusions of Ellinger and Coulson¹⁹ that the development of fluorescence from the non-fluorescent nicotinamide methochloride or the precursor of F_2 by alkalinization and treatment with butanol is due to a rearrangement of the quaternary base into a carbinol, but they believe that F_2 is a carbinol-*isobutanol*-ether. This conclusion is based on the following facts: (a) that the fluorescence of the alkaline aqueous solution is greatly increased by the addition of small amounts of *isobutanol* enough to saturate the aqueous layer, but insufficient to cause a separation of the two layers, (b) that the fluorescence intensity of the *isobutanol* layer increases while standing. The carbinol-butanol-ether is said to break down when evaporated to dryness. An elementary analysis of the crystals yielded values for nitrogen which correspond to about half the amount theoretically required.

The evidence for F_2 being a carbinol-butanol-ether would appear to be inadequate, since the increase of fluorescence on addition of *isobutanol* to the alkalized aqueous nicotinamide methochloride solution is fully explained by the fact that a considerable amount of *isobutanol* favouring the carbinol phase is dissolved in water. This increase in fluorescence intensity is observed when a number of solvents of F_2 , such as methanol, ethanol, amyl alcohol, ethyl acetate (some of them being miscible with water) are added to the alkalized aqueous solution of nicotinamide methochloride or of the precursor of F_2 , but not when organic solvents are added which do not dissolve F_2 , such as ether, petrol ether, pentane, chloroform (Ellinger²⁸). The increase in the fluorescence intensity on standing is explained by the fact that the rearrangement of the quaternary base into the carbinol, induced by the equilibria in aqueous and butanol solutions and the relative solubility of the carbinol in the two layers, is a slow process. Under the conditions used in the assay method as described by Coulson, Ellinger and Holden³⁶, maximum fluorescence of the butanol layer is reached after thorough shaking for five minutes.

There is one experimental fact against the acceptance of the idea that F_2 is a carbinol-butanol-ether. The pigment F_2 can be developed by treating the aqueous alkaline solution of nicotinamide methochloride or of the precursor of F_2 with ethyl acetate in place of butanol²⁸. It seems improbable that ethyl acetate is able to form a carbinol-butanol-ether or a corresponding ether with the carbinol. The fluorescence in the ethyl acetate layer is less intense than in butanol owing to a lower partition coefficient (Ellinger²⁸).

Najjar and co-workers^{33,34,35} stress the apparent discrepancy between nicotinamide methochloride and the non-fluorescent precursor of F_2 , and employ for this purpose the findings of Coulson and Ellinger²⁴ that different aurates are formed from the two products. However, as has already been pointed out, aurates with varying gold content are formed also from trigonelline. Najjar and White³⁵ produce additional evidence in support of their conclusion that the two substances are dissimilar. The precursor of F_2 is said to show a weak bluish fluorescence, and the urinary precursor of F_2 is said to differ when different anti-pellagic agents are ingested. Remeckates obtained from urinary eluates after the ingestion

of nicotinic acid and of nicotinamide are also said to show significant differences in melting points. No crystalline picrate was obtained from the precursor of F_2 recovered after nicotinic acid administration. The weak fluorescence of the urinary precursor of F_2 would appear to contradict the findings of Ellinger and Coulson¹⁹ and of Huff and Perlzweig²⁸. The absence of any specific details of the exciting beam used by Najjar and White³⁵ makes it necessary to assume that Wood glass filtered mercury light was used, that is, a light consisting of about 90 per cent of the 366 m μ and 10 per cent of the 311 m μ lines. If the absorption spectrum of the precursor of F_2 as found by Ellinger and Coulson¹⁹ and by Huff and Perlzweig²⁸ for ' F_2 ' is correct, then the precursor of F_2 cannot be 'fluorescent' under the conditions of the experiment, since the 366 m μ and 311 m μ lines are not absorbed by the aqueous solution. The fluorescence observed by Najjar and White is probably due to impurities. Picrates possessing identical melting points have been found by Ellinger²⁸ from the precursors of F_2 after ingestion of nicotinamide, nicotinic acid, and nikethamide by a human subject. The occurrence of two different Remeckates may be due to the same cause as that of two different aurates. There is at present no evidence for the non-identity of the urinary precursor of F_2 and nicotinamide methochloride and for different F_2 precursors after the ingestion of nicotinamide and nicotinic acid.

Najjar and co-workers^{29,37} have attributed a considerable biological activity to nicotinamide methochloride. It is considered to be a growth factor for *E. coli* and *H. influenzae* and an efficient agent in preventing and curing nicotinamide deficiencies in hamsters and dogs.

The interference with the estimation of aneurin by the thiochrome method by the formation of a bluish fluorescent derivative of the nicotinamide methochloride simultaneously present during the treatment with alkali and ferricyanide was observed by Najjar and Ketron³⁸, and a method was devised to avoid this error. This bluish fluorescent pigment was called F_3 by Coulson³⁹, who considered it to be most probably a N-methyl pyridone derivative of nicotinamide. It seems probable that the same substance was obtained by Ellinger²⁸ from F_{2a} , but not from F_{2a} , by treatment with alkaline ferricyanide. Coulson³⁹ also devised a method for simultaneous determination of aneurin and nicotinamide methochloride.

In addition to the earlier methods, three quantitative procedures for the estimation of nicotinamide methochloride have been devised, by Huff and Perlzweig⁴⁰, by Coulson, Ellinger and Holden³⁶, and by Najjar⁴¹. With the help of these improved methods, a clearer insight was gained concerning the metabolism of nicotinamide in normal persons and its changes in certain diseases (Ellinger and Coulson¹⁸). Only 10-15 per cent of ingested nicotinamide is eliminated as nicotinamide methochloride in the urine by normal persons after a single ingestion, thus it must be emphasized that about four-fifths of the ingested nicotinamide cannot be accounted for³⁸. It remains to determine whether nicotinamide methochloride is the only metabolite of nicotinamide in man and animals which methylates pyridine derivatives, or whether other metabolites such as trigonelline can be found, especially after the ingestion of nicotinic acid.

Ellinger and Coulson¹⁸ examined the effect of the ingestion of nicotinamide, nicotinic acid and other

nicotinamide derivatives on the daily elimination of nicotinamide methochloride, studied the intrinsic and extrinsic factors influencing this elimination and discussed the mechanism of the formation of nicotinamide methochloride. From the relation of the eliminated nicotinamide methochloride to the dietary nicotinamide intake, they suspected the presence of an extra-dietary source of nicotinamide. This supposition was proved to be correct by Ellinger, Coulson and Benesch^{42,43}, who showed that a considerable proportion of the human requirements of nicotinamide can be due to the production of this substance by the intestinal flora, a fact which throws new light on the etiology of pellagra and other nicotinamide deficiencies. Nicotinamide elimination in pellagra was studied by Holt and Najjar⁴⁴, Roberts and Najjar⁴⁵ and Ellinger and Benesch⁴⁶, they found lower elimination of the F_2 precursor in pellagrins than in healthy persons, both untreated and after single and repeated administrations of nicotinamide. A change of these 'saturation curves' was also observed in certain liver diseases (Ellinger and Benesch⁴⁶). Evidence was obtained that ulcerative gingivostomatitis was not due to a nicotinamide deficiency (Coulson, Ellinger and Smart⁴⁷).

'Fluorescence' throughout this paper always means fluorescence in the visible region produced by the primary light used usually for this purpose, namely, long-wave ultra-violet, especially the 366 m μ and 311 m μ mercury lines. It is quite possible that aqueous solutions of nicotinamide methochloride emit fluorescence in the ultra-violet region when excited with rays of about 260 m μ . To investigate this point more complicated instruments, a quartz monochromator and an ultra-violet spectrograph are necessary. When fluorescence is mentioned, the absorption spectrum of the substance in question and the wave-length of the exciting beam should be given to explain whether under the conditions of the experiment fluorescence can be produced. To characterize the fluorescence qualities of a substance the 'fluorescence efficiency', that is fluorescence intensity per absorbed light quant (Wawilow⁴⁸), should be given in addition to the exciting wave-lengths and the absorption spectrum. Since absolute values of the fluorescence efficiency are difficult to obtain, it is advisable to relate the measured fluorescent intensity when half the exciting light is absorbed to that of an aqueous quinine sulphate solution of the same molar concentration under the same conditions as standard. The knowledge of the fluorescence efficiency makes it possible to judge whether changes of fluorescence intensity which occur frequently, for example, by alterations of pH, are due to a shift of the absorption band or to a change in fluorescence efficiency.

'RUBBER ACID' DAMAGE IN FIRE HOSES

By DR A C THAYSEN, H J BUNKER and Miss M E ADAMS

Microbiological Section of the Chemical Research Laboratory, D S I R, Teddington

IN a brief reference, Crosby, Fiske and Forster¹ mention that a common cause of hose failure in rubber-lined fire hoses may be due to sulphuric acid formed from sulphur present in hoses when these are not properly dried. Such damage, apparently, was almost unknown in Great Britain before the War, but has recently been much in evidence. According to Phillips², 'rubber acid' is produced, and its damage observed chiefly in fire stations which lack adequate draining and drying facilities. It would appear to affect primarily, if not exclusively, rubber-lined fire hose.

When rubber-lined hose is stored after use, without preliminary draining and drying, there is invariably left in it a certain amount of water, and when such hose is examined during storage, it is found to contain a liquid, commonly the amount is no more than a quarter of a pint. This liquid is not infrequently discoloured brown. It is often slightly turbid and

markedly acid, the degree of acidity tends to increase with duration of storage. On examination the acid proves to be sulphuric.

When rubber acid is accidentally spilt over the canvas surface of the hose, or over any other cellulosic fabric, rapid tendering occurs, a process which becomes accelerated with the drying off of the fabric. When spilt over a concrete floor the rubber acid may cause corrosion of the floor surface and evolution of carbon dioxide gas bubbles.

Phillips² has given some data illustrating the importance of the damage caused by rubber acid to the hose, and as an immediate remedy advocated thorough draining of the hose after use. In a subsequent communication³, Phillips *et al* describe an examination of three hundred hose bursts, representing damage throughout Great Britain. More than 50 per cent of these bursts were due to rubber acid damage. They record also that rubber-lined hose of British, Canadian and American origin are equally subject to the fault, and that the concentration of sulphuric acid found in the hose liquor may reach a figure of about 1 per cent.

Phillips *et al* state that the opinion has been advanced that acid production is due to the inclusion in the hose rubber of an excessive amount of free sulphur, which in the presence of water and air becomes oxidized to yield sulphuric acid. However, the well-known resistance of elemental sulphur to auto-oxidation at atmospheric temperatures seemed, on the face of it, to preclude this explanation. On the other hand, micro-organisms had been observed in numerous samples of hose liquid, and since there is well-established evidence to show that in the presence of certain micro-organisms, elemental sulphur can be oxidized to sulphuric acid at atmospheric temperatures, it was logical to keep this possibility in view and to ask the Chemical Research Laboratory to examine it.

The initial samples of hose liquor were drawn under aseptic conditions from rubber-lined hoses from three fire stations in the Kingston (Surrey) district.

Details of these samples are given in Table 1.

TABLE 1

Station	Sample No	Appearance of liquid	Reaction of liquid to litmus	pH of liquid	Date hose last used
A	1	Colourless	Neutral	7.1	2 days previously
	2	Faintly discoloured and turbid	Neutral to only slightly acid	7.0	2 days previously
	3	Strongly yellow and turbid	Acid	1.0	At least 6 months
B	4	Colourless	Neutral to only slightly acid (about 1 gallon)	7.0	At least 7 days
	5	Colourless and somewhat turbid	Neutral to only slightly acid (about 1 quart)	7.1	At least 7 days
C	6	Brown	Acid	1.0	At least 1 month

The presence of micro-organisms in the various samples was confirmed both by direct microscopic examination and by cultivation on ordinary nutrient agar, wort agar and thiosulphate agar, the latter being a medium free from organic substances and recom-

mended by Waksman⁴ for the cultivation of sulphur-oxidizing bacteria.

The microflora taken from the six samples of rubber acid and found capable of growth on ordinary nutrient agar comprised several forms, all of them with their natural habitat in soil and water. Their numbers ranged between two and fifteen million cells per ml of hose liquor, except in sample 6, where they were completely absent. The highest number occurred in sample 2. None of them was of a type capable of oxidizing elemental sulphur.

On wort agar only four types of fungi developed: a black fungus so far unidentified, another with white mycelium, possibly a *Cephalosporium* species, a black *Dematium* species and a pink *Torulopsis* species. Their numbers did not exceed 70,000 cells per ml in any of the rubber acid samples, and were no more than 20 per ml in sample 6.

The *Cephalosporium* species was found in samples 1 and 2, the unidentified fungus in samples 3, 4, 5 and 6, the *Dematium* species in samples 1 and 4 and the pink *Torulopsis* species in sample 4. Only the black fungus, therefore, could have been associated with acid production. However, since it did not appear on any of the thiosulphate agar media, it is unlikely, to say the least, to have played a major part in sulphur oxidation.

The organisms which grew on the thiosulphate agar were restricted to no more than five types, all of them short, non-spore-forming rods. Their numbers in the various acid samples were very much of the same order, ranging from 13 to 19 million cells per ml of hose liquor, except in sample 6 where only 5 million cells were counted.

Each of these types was tested for its sulphur-oxidizing power by inoculating it into a medium containing inorganic salts and free sulphur. On this medium only two of them, isolated from hose liquor samples 3 and 6, grew rapidly, and in less than a week rendered the liquid turbid and acid, with a drop in the original reaction of the medium from pH 4.6 to pH 1. The acid produced was identified as sulphuric acid. Of the remaining types of short rods growing on thiosulphate agar, it should be mentioned that they grew well also on ordinary nutrient agar. Those from liquors 3 and 6, which produced acid from elemental sulphur, did not do so.

The remaining four samples of hose liquid, from which sulphur-oxidizing bacteria had not been isolated by the direct method employed, were inoculated into an inorganic liquid medium containing free sulphur. It was suspected that the failure to isolate sulphur-oxidizing bacteria from these samples might have been due to their containing too few cells. By introducing the original hose liquors into a medium specially adapted for the growth of sulphur-oxidizing bacteria, it was hoped to increase their numbers and thus to facilitate their isolation. However, after incubation of the inoculated special media for 14 days at 30°C only one of these, that inoculated with hose liquor No 4, gave rise to acid. From this sample it was possible to isolate typical sulphur-oxidizing bacteria. The others remained unchanged in reaction and showed no growth of micro-organisms. It is probable, therefore, that these samples Nos 1, 2 and 5 had not contained the organisms looked for.

It had been possible, therefore, to isolate sulphur-oxidizing bacteria from only 50 per cent of the hose liquors examined, implying either that these organisms may not be necessary for acid formation, or that these samples of liquors in which the organisms had

not been found, and presumably had not been present, would have failed to become acid in any event. On the available information it is not possible to decide which of the two alternatives is correct, though one deduction that can be made from the collected data seems to point in favour of the latter explanation.

The inconclusiveness of the results thus far obtained, which incidentally were unlikely to be improved upon by an analysis of further samples of hose liquor, made it desirable to test the hypothesis of a microbiological origin of rubber acid from a different angle, and to establish whether water introduced into rubber-lined hose would invariably become acid, if it contained sulphur-oxidizing bacteria.

An experiment was set up for this purpose in which tap water containing sulphur-oxidizing bacteria was introduced into sections of hose about 2 ft long. Sections from three hoses were chosen, two from new hoses and the other from a hose already in service which had developed rubber acid. Each section was bent in the shape of a U and into each, 25 ml. of test water, containing test bacteria, were introduced. The sections were then closed with clamps to reduce evaporation and incubated at room temperature. Each section was opened daily to admit oxygen and also shaken to keep the inner rubber surface wet. As control, a sterile section was taken from each hose. Into each of these, 25 ml. of sterile tap water was introduced, but no bacteria.

Table 2 shows the rate of change in pH values of the water contained in the various sections during 14 days of incubation.

TABLE 2

CHANGES IN pH VALUES OF WATER KEPT IN RUBBER-LINED FIREHOSES

No	Description	pH of water after incubation for			% of free sulphur in hose
		0 days	1 day	14 days	
1	New hose (sterile)	7.4	7.4	7.4	0.2
1a	" " + sulphur-oxidizing bacteria	6.0	6.2	1.6	0.2
2	New hose (sterile)	7.4	7.4	7.4	<0.1
2a	" " + sulphur-oxidizing bacteria	6.0	6.2	6.2	<0.1
3	Old hose (sterile)	7.4	7.4	7.4	0.1
3a	" " + sulphur-oxidizing bacteria	6.0	6.4	2.7	0.1

There is an interesting deviation in the expected results tabulated in Table 2. One of the new hoses apparently did not respond as expected to the presence of sulphur-oxidizing bacteria. This was a hose in which the free sulphur present amounted to less than 0.1 per cent. Apart from this it was possible to confirm that the presence of sulphur-oxidizing bacteria is essential for the production of acid hose liquor.

In a further experiment with sections of the No. 2 new hose in which, in addition to sulphur-oxidizing bacteria, free sulphur was added to the water introduced into a sterile section, it was possible to show that the failure of acid production was due not to any inhibitory properties possessed by this hose, but to the presence of insufficient free sulphur. For in this additional experiment the pH value of the water contained in the section dropped to below 1.2 in the course of 14 days.

It is clear, therefore, that there are two factors governing acid production in hose: first the presence or absence of the relevant bacteria, and secondly,

the presence of a sufficiency of free sulphur. This latter apparently should not fall below 0.1 per cent, calculated on the rubber lining. If the figures of Table 2 may be taken as substantially correct, acid production will be proportional to the percentage of sulphur present, other factors being favourable.

The presence or absence of sulphur-oxidizing bacteria will probably be governed largely by the type of water passing through hose when in use; and it was thought relevant, therefore, to examine fire-fighting water supplies for the presence of these organisms.

On inquiry it was found that much of the water available to the National Fire Service in the London district is taken from static supplies, these being replenished from the River Thames, or from local canals and ponds. Water taken direct from the mains is not used when other supplies are available.

An analysis of twenty-five samples of water from different sources of supply, including mains water, revealed that thirteen contained sulphur-oxidizing bacteria. Only two of the samples of mains water out of six examined contained these organisms. The percentage, therefore, of the crude waters used which contained these bacteria was no less than 58 per cent. The observation may perhaps give a clue to the frequency with which rubber acid is likely to be found in hose.

The presence of sulphur in rubber-lined hoses was found on inquiry to vary very considerably. Pre-war hose specifications, according to Phillips (*l.c.*), limited the free sulphur content in hose lining to 1 per cent in Great Britain and to 1.25 per cent in the United States. But these data are not a reliable guide, for recent analyses of twelve American samples showed the content to vary between 0.06 and 0.7 per cent. Similar variations are likely to occur in hose made in Britain and in Canada. From the data given in Table 2 it would appear that a free sulphur content of 0.1 per cent is sufficient to produce some acid, and that 0.2 per cent causes marked acid production. A permitted minimum of 1 per cent of free sulphur is therefore a gross excess, and can be expected to lead to acid production whenever the appropriate bacteria are present.

Conclusions The conclusions to be drawn from the experiments which have been carried out would appear to be that

The production of rubber acid in hose is due to the activity of sulphur-oxidizing bacteria of the *Thiobacterium thiooxidans* group.

Such acid will invariably be formed in rubber-lined hose which is stored with the linings wet, when the responsible bacteria are present and when the free sulphur content of the hoses exceeds 0.1 per cent.

If acid production is to be prevented, it is necessary to ensure, either that the rubber-lined hose is stored dry, or that its content of free sulphur is less than 0.1 per cent.

The alternative of preventing the introduction of the causal bacteria does not appear practicable, since the water used in fire-fighting is a frequent habitat of these bacteria.

In a series of additional experiments it was established that various organic sulphur compounds, commonly used in the vulcanization of rubber, failed to give rise to acid production, even in the presence of sulphur-oxidizing bacteria.

Thanks are due to the officers and men of the National Fire Service, and especially to Company Officer W. E. Gage, Hose Officer, No. 38 Fire Force,

who assisted us in obtaining the necessary experimental material and certain data required for this investigation. The work was carried out on behalf of the Director of Scientific Research, Ministry of Home Security, and is published with the approval of the Department of Scientific and Industrial Research and the Ministry of Home Security.

OBITUARIES

Lord Dawson of Penn, P.C., G.C.V.O., K.C.B., K.C.M.G.

THE death on March 7 of Lord Dawson at the age of seventy-nine has removed from the ranks of the medical profession one of its most eminent members. Lord Dawson symbolized in his own person the many different services the profession can render to the community. He had been physician to several members of the Royal Family. He was the perfect consultant combining hospital appointments with private practice, always at the service of his patients at whatever inconvenience to himself. To the House of Lords, to which he was elevated in 1920, he brought fine qualities of statesmanship and oratory, and he did invaluable work there in presenting to the public the medical point of view. His scientific eminence was reflected in the many honours conferred on him by universities and medical societies all over the world.

Lord Dawson was a prolific writer and lecturer on a wide variety of medical subjects. He took a prominent part in the organization of the medical services and the famous Dawson Report, produced under his

chairmanship by the Consultative Council on Medical and Allied Services appointed at the time of the creation of the Ministry of Health in 1919, is a milestone in the history of medical services. If the Government had acted upon the advice offered in that Report we might have been saved many of the problems the profession is facing to-day. Lord Dawson's wisdom in guiding the domestic affairs of his profession was recognized by his election to the presidency of the Royal College of Physicians during 1931-38 and to the presidency of the British Medical Association in its centenary year in 1932. He was recalled to the presidency of the British Medical Association in 1943 to lead the profession in the present critical stage of the development of the medical services of Great Britain.

To all his work Lord Dawson brought a rare vigour and wisdom and sympathy. He saw the practice of medicine as a means of making people healthy and happy. His charm and courtesy endeared him to all with whom he came in contact, both professionally and socially, and his pervasive influence will be sorely missed by the medical profession and the scientific world.

WE regret to announce the following deaths:

Sir Charles Bell, K.C.I.E., C.M.G., an authority on Tibet, aged seventy-four.

Sir George Humphreys, K.B.E., formerly chief engineer to the London County Council, president in 1930 of the Institution of Civil Engineers, on March 9, aged eighty-one.

Sir Hanns Vischer, C.M.G., C.B.E., honorary secretary-general of the International Institute of African Languages, on February 19, aged sixty-eight.

Prof. H. H. Whetzel, professor of plant pathology in Cornell University, on November 30, aged sixty-seven.

NEWS and VIEWS

Helium for the Royal Society Mond Laboratory

THE National Research Council of Canada has recently made a gift of 2,000 cubic feet of helium gas to the Royal Society Mond Laboratory at Cambridge. This amount of gas will enable the Laboratory to recommence research on very low temperature problems and on a scale which will allow the full resources of the Laboratory to be employed. In the whole field of physics, the temperature region close to the absolute zero remains one of the most fruitful for investigation. The low-temperature problems which received most attention before the War were those of superconductivity, magnetic cooling and the properties of liquid helium itself. These are, however, only the more prominent aspects of a wider field of investigation. Many mechanical, electrical, magnetic and optical phenomena, which are either partially or completely obscured by thermal agitation at room temperature, stand out clearly and undisturbed in the quiet region from 5° absolute down to 0.01° absolute which is attainable with liquid helium.

Grants for Scientific Investigations and Publication

THE Royal Society has now been informed that the Treasury has made provision in the estimates for the fiscal year 1945-46 for the following grants which are

administered by the Royal Society: for scientific investigations, £14,000; for scientific publication, £7,000; for scientific congresses, £1,600. In view of the greater amounts to be available if these estimates are accepted by Parliament, and of present changing conditions, the Royal Society has decided that more frequent allocation is desirable. The last dates, therefore, in 1945, for receiving applications for grants from the Parliamentary Grant-in-Aid for Scientific Investigations will be March 31, July 31 and November 30, and the last dates for receiving applications for grants from the Parliamentary Grant-in-Aid for Scientific Publication will be June 15 and November 15.

Cosmic Ray Studies in the Pamirs

A GROUP of scientific workers from the Lebedev Institute of Physics, Moscow, has left for the Pamirs to study the composition of cosmic rays at high altitudes. The expedition is under the direction of Prof. Skobeltsyn, of the U.S.S.R. Academy of Sciences, and will continue studies that have been carried on for several years on Mt. Elbrus by workers from the Atomic Nucleus Laboratory. The main object of the expedition is to determine the part played by heavy particles and secondary mesons first discovered in the study of cosmic radiations in 1937. Cosmic

radiations have two sharply defined components—a hard component consisting of mesons possessing great energy and a soft component including positrons and electrons. It is known that the soft component, at any rate at sea-level, is genetically connected with the hard component, being apparently generated by the latter. At great altitudes the presence of an unbalanced component has been discovered, namely, radiation that is not directly connected with the hard component. The study of cosmic radiations at great heights is therefore of great importance for the understanding of cosmic radiations as a whole. The question of secondary mesotrons and other strongly ionized agents causing ionization impulses is of great interest. The problem of the generation of secondary mesotrons has gained in significance in recent times.

In order to study mesons, the expedition will make use of an improved form of 'proportional telescope'. In studying cosmic rays at great heights, they will take into consideration 'atmospheric rain', a phenomenon of cosmic rays discovered by a French physicist, P. Auger. Skobeltsyn has studied all the available experimental data, especially those obtained in the Elbrus Laboratory, and has come to the conclusion that a considerable proportion of the impulses are due to processes other than 'Auger's rain'. The expedition will try to prove this by the method of coincidences. An important part of the work of the expedition will be the study of the transition effects of the soft component, that is, the processes which occur when rapid protons and electrons leave matter with one atomic weight and enter the orbit of substances with a different atomic weight. The cycle of studies devoted to these particular effects, which was begun before the War, will be continued, employing greatly improved methods which the Atomic Nucleus Laboratory has recently evolved.

Educational Needs in Liberated Countries

THE sixteenth meeting of the Conference of Allied Ministers of Education was held on March 7 under the chairmanship of the Right Hon. R. A. Butler. The Belgian Minister of Education, M. Buisseret, made a special visit to London in order to attend. Mr. Butler stated that considerable progress has been made towards the establishment of a United Nations organization for educational and cultural reconstruction, and it was announced that it would be possible, after the San Francisco meetings, to make proposals for the final constitution of the new organization. M. Buisseret presented a statement to the Conference stressing the difficult position which has resulted from the Nazis' forceful educational propaganda among teachers and in schools, especially in the small, mainly German-speaking areas of Belgium, which in the course of the occupation had been annexed to Germany. It was pointed out that similar problems might arise in other countries which had suffered occupation. The Conference was informed that a new Commission has been formed "to collect information from liberated countries and elsewhere about the educational needs of, and the work being done for, children and young people requiring special educational treatment, to make the necessary contacts with other bodies engaged on similar activities and to make recommendations to the Conference as to how the information can best be made available and assistance given if desired to the Allied Governments." Mr. J. A. Lauwerys has been appointed to direct the inquiry, and will have his headquarters at 3-5 Salisbury Square, London, E.C.4. The Con-

ference adopted the following resolution, and decided that it should be communicated to the Allied Governments through their delegations: "The Conference of Allied Ministers of Education, having considered reports from liberated territory, record their unanimous view that, the need for the supply of raw material for educational purposes, and in particular for school books, is of paramount importance. Unless such supplies are made available the Conference believes that the resumption of educational activities will be greatly delayed and additional hardship for the children, students and parents in liberated territories will result."

Restoration of Libraries

UNDER the auspices of the Conference of Allied Ministers of Education, a committee has been set up to administer the organization and premises known as the Inter-Allied Book Centre, 3-5 Salisbury Square, London, E.C.4, where books can be received and systematically arranged for ultimate allocation to libraries in Great Britain and abroad which have been damaged or destroyed during the War. Already more than a million books, ranging over the whole field of knowledge, have been set aside, by action of the Government, from collections made primarily for salvage purposes. The collection includes books of every kind, but the proportion of modern technical, scientific, commercial and legal works is low. Many libraries will urgently need sets of the more important periodicals, particularly the back numbers of journals and transactions. Those unable to give books or periodicals can support the general scheme by money contributions, which will be used entirely for the purchase of books and periodicals, but so many books have been destroyed, or are in short supply, that the need is for books rather than money. It is generally thought that the committee of allocation should have a free hand to decide the ultimate destination of all books received, but if a donor urgently desires to give to a particular country, or even a particular library, he is asked to communicate with the director of the Book Centre. Bodies which are already collecting books for specific countries or institutions are asked to supply the director with lists of books and periodicals which they propose to distribute, so that they can be taken into account by the Centre in making its own distribution. Donors are asked to send to the director of the Centre, Mr. B. M. Headicar, lists of the books available, carriage will be refunded, if desired, on all books presented.

Royal Institute of Chemistry

AT the sixty-seventh annual general meeting of the Royal Institute of Chemistry held on March 12, at the Institute, 30 Russell Square, W.C.1, Prof. Alexander Findlay, the president, in moving the adoption of the annual report, emphasized the growing opportunities for men of science to bring about a better balance between science and politics and between knowledge and power. The tasks of Government and the formation of a national and international policy which will secure the fullest and most complete development and expression of human nature, when beauty and goodness merge and blend together with truth, depend in part on values other than the scientific, and involve problems which cannot be solved merely by the application of the laws of natural science. But in securing the material well-being of the people and in advancing industrial pro-

perity, science is all-important and, in Prof Findlay's opinion, representatives of scientific institutions on the Parliamentary and Scientific Committee are playing a particularly important part in keeping the Government informed regarding the discoveries and applications of science to human and industrial well-being, and in providing a scientific method of approach to the problems of national administration, a method infused with the spirit of truth rather than of prejudice or party partisanship.

Prof Findlay stated that the roll of membership of the Institute has increased by 523 to 9,227, and the register of students by 205 to 1,225 during the past year. He also referred to the greater collaboration among the various organizations of chemists and the better co-ordination of their activities, in which representatives of the Institute have continued to play their part. He congratulated the Chemical Council on having gained from industrial firms and private subscribers greatly increased financial support for chemical publications. During the sixty years since the Institute was incorporated by royal charter, its membership has increased twenty-fold and there has also taken place remarkable expansion of the activities of chemists. The time has now come to reformulate its aims and interests and to adapt its organization so as the more effectively to achieve its aims and fulfil its responsibilities, proposals for modifying the charter and by-laws are to be laid before the members in due course. Reference was made to the retirement of Mr Richard B. Pilcher, who had been secretary for fifty years and for forty-five years registrar and secretary, and the appointment of Dr H. J. T. Ellingham as secretary and Mr R. L. Collett as registrar. Prof Findlay was re-elected president.

Pedigree of Fossil Man

PROF RUGGLES GATES has produced a very concise and interesting article on the pedigree of fossil man (*Amer J Phys Anthropol*, 2, No 3, Sept 1944). He reviews the opinions of others, discusses modern tendencies and viewpoints, and summarizes his own conclusions. So long as the data supplied relative to the finds of prehistoric man are reliable, the conclusions arrived at by the physical anthropologists must, of course, be treated with great respect. But unfortunately, really well-authenticated and documented discoveries of prehistoric skeletons are more than rare. For example, Prof Ruggles Gates says: "The evidence of the Committee which investigated the Swanscombe parietal and occipital shows that stratigraphically it is one of the best authenticated of all human remains, and geologically the evidence of the age of the gravels in which they were found is very complete." In the sense that the exact horizon whence came the bones is known, this is certainly true, but it is not enough, for in those Swanscombe gravels both Acheulean and Clactonian industries occur mingled. To say the least, it is still possible that the prehistoric folk who made the *coup-de-poung* industries were entirely distinct from those flake-tool makers who produced the Clacton, Levallois and other flake industries. A study of distribution maps strongly suggests that such a distinction should be made. Now the early flake-tool folk were the ancestors of the Mousterians, that is, of Neanderthal man, whereas the *coup-de-poung* makers appear to have quite another story—perhaps an African one—and it is thus still impossible to be certain to which of these two cultural facies the Swanscombe bones belonged. It is not until problems like this—

purely matters for the prehistorian to settle—are resolved that the physical anthropologist can satisfactorily do his job. Bearing in mind this warning note, Prof Ruggles Gates's paper makes interesting and informative reading. He is trying to give answers to just those questions many would like to have elucidated, among other interesting conclusions he places Neanderthal man, in accordance with Weidenreich, in the chain of development from *Pithecanthropus* and *Sinanthropus* to "the modern type of man". Not all anthropologists would agree.

Length of Small Intestine ✓

THE capacity of the human body to withstand remarkable injury or loss of what may seem to be essential organs is continually astonishing those who have to deal with injuries sustained in war and peace or with the results of surgical operations. C. C. Holman (*Lancet*, 597, Nov 4, 1944) has reported the instance of a woman who, having survived the removal of her uterus and of the breast for cancer ten and six years earlier respectively, had to sustain, at the age of fifty-six, the removal of twenty feet of her small intestine. A lateral anastomosis was performed between the jejunum and the transverse colon. The patient recovered and three months later had gained 2 lb in weight. A year after the operation she weighed rather more than before her operation and was doing the parish work as a clergyman's wife.

In an Annotation on this case, the *Lancet* says that people have survived, for several years at least, with only 3 ft of combined duodenum and jejunum and no ileum. It has been calculated (H. E. Haymond, *Surg Gynec Obstet*, 61, 693, 1935) that removal of up to one third of the total length of the small intestine could be followed by return to normal function, but that poor results might follow removal of more than half of it, or eleven feet in average people. It is pointed out, however, that the length of bowel removed gives no true indication of the length which remains, because the total length of small intestine varies between 10 ft and 28 ft 4 in, according to J. Bryant (*Amer J Med Sci*, 167, 499, 1924), who measured the small intestine at autopsy in 160 adults. When the gut is alive, it is a great deal shorter, possibly half the length measured at autopsy or less. Another case, reported by J. A. Cosh in the same issue of the *Lancet* (p. 596), was less fortunate. This was a man aged sixty-seven, from whom all the small intestine was removed except the duodenum and about 3 ft of the jejunum. For about eight months he had fairly good health, but then became ill and died twelve months after the operation.

Announcements

PROF BENGT EDLÉN, of Lund Observatory, Sweden, has been awarded the Gold Medal of the Royal Astronomical Society for the year 1945 for his identification of the origin of the principal lines in the coronal spectrum.

THE Council of the University of Sheffield has appointed Dr Harry Moore to the chair of glass technology in succession to Prof W. E. S. Turner, who is to retire at Christmas 1945, Dr H. A. Krebs to the newly created chair of biochemistry, and Mr A. E. Bender to be research biochemist in the Department of Pathology, to work in association with the Sheffield Radium Centre.

Structure of Boron Hydrides

As recently shown¹, the interpretation of polyatomic structures does not require the hypothesis of resonance among several idealized valence-bond structures, a speculative application of the quantum-mechanical conception of resonance, which is in disagreement with numerous facts. They are accounted for by the principles of the classical (atomic and electronic) structural theories. The boron hydrides have been represented as resonance hybrids involving structures with one-electron linkages. Longuet-Higgins and Bell², in a most interesting and important discussion, have given convincing evidence that the introduction of the unique and theoretically unlikely one electron linkage between two unequal atoms is unnecessary, and that the boron hydrides should be represented by the bridge formulæ of type

containing hydrogen bonds³.

Since hydrogen bonds are generally formed between atoms with unshared electrons and hydrogen atoms belonging to strongly polar linkages, whereas no unshared electrons are available at the B atom and the B—H linkage may be only slightly polar, Longuet-Higgins and Bell prefer to distinguish the linkages in the boron hydrides from other hydrogen bonds as resonance links. This implies a stabilization due to resonance involving no electron linkages. It is assumed that electrons belong to the orbitals of more than two atoms, that is, are non-localized

However, two factors should be essential for the formation of the electrostatic hydrogen bond: (1) presence of opposite charges at the two atoms, (2) the possibility of a sufficiently close approach of the atoms. Decreasing size of the atoms and absence of other atomic orbitals sterically inhibiting the approach of the second atom will facilitate the formation of a hydrogen bond. Such favourable conditions exist particularly in the case of small and unshielded atoms such as H, B, F, O, etc., the presence of unshared electrons is incidental. The charges at the B and H atoms in boron hydrides may be small, but this could easily be compensated by the presence of two linkages and the rather short B—H distances, which should not be longer than 1.6 Å.

It is not justifiable to assume that the H atom in BH₃ is unlikely to form a hydrogen bond of an essentially electrostatic nature with the B atom of another molecule, because this ability decreases rapidly in the series HF, H₂O, H₃N, H₄C. The charge at the H atom being positive will decrease in the former three molecules to become negligible, although possibly already negative in CH₄.⁴ Certainly in BH₃,

it should be negative* and again greater. Moreover, in contrast to the completely shielded C atom in CH₄, the B atom, like the F, O, and N atoms, will allow the approach of another H atom.

The formation of stable ring structures rather than of long-chain structures by hydrogen bonds will depend on steric influences, including the ability of the participating atoms to form sufficiently strong linkages at the angles required. Steric conditions being satisfied, ring structures of smallest polymerization degree will always be more stable because of the increased stability due to an additional hydrogen bond and an increased polarization of the linkages involved. Thus, carboxylic acids possess a dimer ring structure, *ortho*-nitrophenol and numerous similar substances form intramolecular rather than intermolecular hydrogen bonds.

The formation of an electrostatic linkage will, of course, not only depend on the size of the atoms essentially determining the interatomic distance, but also on the degree of their charges, which will increase in the series (+)B—H(−) < (+)Al—H(−) < (+)Ga—H(−) and compensate for the lengthening of the interatomic distance.

The interpretation of the unexpectedly complicated infra-red spectrum of diborane has offered considerable difficulty⁵. An analysis based on the suggested structure containing different covalent B—H and electrostatic B—H linkages should be of interest. However, a decision between these structures is only possible by a comparison of analyses based on both the 'symmetrical' and the 'unsymmetrical' bridge structure.

The stability of boron hydrides does not require the introduction of a new type of resonance involving no electron linkages.

A BURAWOY.

College of Technology,
Manchester
Dec 21

* During a discussion following a lecture by Mr R. P. Bell on November 30, Prof. J. Kenner independently directed attention to this point and emphasized its importance in relation to this problem.

² Longuet-Higgins and Bell, *J. Chem. Soc.*, 250 (1943).

³ For original literature, see ref. 2.

⁴ Timm and Mecke, *Z. Phys.*, **98**, 363 (1935). Fuchs and Wolf, "Die elektrische Polarisation", *Hand- und Jahrbuch der Chem. Phys.*, 356 (Leipzig, 1935). Trieschmann, *Z. phys. Chem.*, **32B**, 22 (1936). Cf., however, Smyth, *J. Phys. Chem.*, **41**, 215 (1937).

⁵ Stitt, *J. Chem. Phys.*, **9**, 780 (1941).

THE chief contention put forward in our earlier paper was that in diborane and similar molecules there were pairs of hydrogen atoms which occupied a special position in linking together different parts of the molecule. We agree with Dr Burawoy that the formulation of these links as resonance hybrids represents only one way of describing this state of affairs: for example, a molecular orbital treatment of the system would not involve the use of the resonance concept. On the other hand, we doubt whether this linkage can be regarded as an electrostatic 'hydrogen bond' of the type met with in HF, H₂O and NH₃. The tendency to this type of dipole association decreases rapidly along the series FH, —QH, > NH, C≡H, and it would be remarkable if it appeared again to a high degree in >BH. It is, of course, conceivable that the BH link has a considerable dipole with the negative end on the hydro-

gen atom, but it is not likely that this would lead to the formation of a stable dimer showing no tendency to further polymerization. A much more likely result would be the formation of an indefinite series of polymers, as is the case with H_2O , HF and NH_3 . It is improbable that the small size of the boron atom is a determining factor, since the hydrogen compounds of aluminium and gallium dimerize as well as those of boron.

If B_2H_6 did contain electrostatic hydrogen bonds, the two central hydrogen atoms would not be equidistant from the two boron atoms. As Dr Burawoy suggests, information on this point might be obtained from the vibrational spectrum of diborane, though the differences in symmetry involved are not such as to produce markedly different selection rules for the symmetrical and unsymmetrical models. However, we have recently made detailed calculations of the normal vibrations of a B_2H_6 molecule containing

ing a symmetrical bridge $\begin{array}{c} \text{H} \\ \diagdown \quad \diagup \\ \text{B} \quad \text{B} \\ \diagup \quad \diagdown \\ \text{H} \end{array}$, and have

obtained excellent quantitative agreement with the observed infra-red and Raman spectra¹. This agreement makes it unlikely that the central hydrogen atoms are unsymmetrically placed.

Effect of Concentration on the Free and Titratable Acids of Hydrogen Bentonites Sols

HYDROSOLS of hydrogen clays and hydrogen bentonites show a marked acid character and give potentiometric and conductometric titration curves with bases having definite inflexion points and breaks^{1,2,3}. A linear relation between the H^+ -ion concentration C_{H^+} , and the concentration of the colloid, C , was observed by Wiegner and Pallmann⁴ in the case of dilute sols having concentrations up to about 0.3 per cent. At higher concentrations the slope, dC_{H^+}/dC , progressively decreased. Some interesting effects of the concentration of the colloid on the H^+ -ion concentration of the sol as well as

the amount of the acid calculated at the inflexion point of the potentiometric titration curve with sodium hydroxide have been observed in the case of a hydrogen bentonite, Kashmir-B, isolated from a deposit of bentonite in Kashmir. X-ray analysis showed that Kashmir-B did not probably contain any mineral other than montmorillonite⁵.

Hydrogen, quinhydrone and antimony electrodes were used for measuring the pH. A 'spear type' quinhydrone electrode prepared as described by Sanders⁶ was also used in the case of very concentrated sols and pastes.

Several determinations of the pH were made at each concentration. These are shown on the accompanying scatter diagrams drawn separately for two ranges of concentrations, 0.69–2.2 per cent and 2.2–16.2 per cent. The full curve shows the average C_{H^+} at the various concentrations.

C_{H^+} increases almost linearly with C until the latter attains a value of about 0.2 per cent. Beyond this point, and up to a concentration of about 2 per cent, the slope, $dC_{\text{H}^+}/dC (= \alpha)$, gradually diminishes. A sudden decrease in the cataphoretic velocity and a rapid fall of the equivalent conductivity were previously observed⁷ at a concentration of about 0.2 per cent of the same hydrogen bentonite sol.

The slope, α , increases at concentrations higher than 2 per cent, and a steep rise and an inflexion in the $C_{\text{H}^+} - C$ curve is observed at a concentration of about 10 per cent. Beyond this concentration the slope again decreases.

The progressive decrease in α at moderate concentrations possibly indicates a secondary adsorption of increasing numbers of mobile H^+ ions of the double layer⁸. The increase in the slope and the inflexion observed at higher concentrations are to be

attributed to a re-liberation or 'mobilization' of some of the secondarily adsorbed H^+ ions by strong fields of force which operate as the individual double layers overlap. The formation of some sort of a structure in the system is indicated. The viscosity of the sol has been found to increase rapidly with the concentration, and the system becomes thixotropic (the sol sets in about three hours) at approximately the same concentration at which the sharp rise in the H^+ ion concentration occurs.

The potentiometric titration curve of the sol with sodium hydroxide has a weak monobasic acid character and shows a marked inflexion at pH 8.5. The amount of the acid (T) neutralized at the inflexion point increases from 81.0 to 103.0 m.e. per 100 gm. of the oven-dried hydrogen bentonite as the concentration increases from 0.25 to 8.8 per cent. T increases with C at a much smaller rate than C_{H^+} , especially in the range of concentrations where the inflexion in the $C_{H^+} - C$ curve is observed. The increase in T with C is due to factors other than those responsible for the variations in the base-exchange capacity of hydrogen clays which have been observed when the sols are titrated with different bases, and in the presence and absence of salts^{9,10}. Assuming that aggregation or structure formation in the concentrated sols causes a decrease in the available surface, a decrease instead of an increase in T would be expected at the higher concentrations if the interaction with the base were confined to the outer surface of the particles.

This work has been carried out with the aid of a grant from the Imperial Council of Agricultural Research, India.

'Figure of Merit' of X-Ray Tubes

At the Leeds meeting of the X-Ray Analysis Group of the Institute of Physics¹ I gave certain figures for the comparative speeds of photographs using a Philips tube, a Shearer gas-tube and the 5 kW filament tube at the Davy Faraday Laboratory.

In justice to the commercial tube makers, I ought to make it clear, as I hoped I had made it clear at the meeting, that the Philips tube I had used for purposes of comparison (the only one available to me at the time) was already eleven years old and had, in fact, since 'died'. The Shearer tube was just as old, but demountable tubes never die, they only fade away, when it becomes desirable to replace them

by a more modern design. The tests I carried out were also made under particular conditions, that is, using a $\frac{1}{2}$ mm diameter cylindrical collimator and a rotating single crystal. I have since had the opportunity of repeating these and other tests using a more modern (just pre-war) Philips tube and other commercial tubes, and I find that, in the same exposure time, the Shearer tube still gives the most intense single-crystal photograph using copper K radiation, but the difference is smaller.

The gas-tube focus is (as used in projection, and under our running conditions) about 2 mm $\times$ 1 mm, and a $\frac{1}{2}$ mm cylindrical slit therefore wastes at least seven-eighths of the tube output in the required direction. If a still finer slit were to be used for crystals having large unit cells and therefore requiring high resolution of reflexions on the photographs, the wastage of output would be even greater, but for powder spectroscopy, for which a 2 mm $\times$ $\frac{1}{2}$ mm straight slit could be used, it would be much less.

I strongly agree with Sir Lawrence Bragg that manufacturers should give some 'figure of merit', which should indicate both focal spot size and comparative output of the various tubes now made. The principal advantages of the gas-tube are the purity of its radiation even after long running, the low input (about 400 watts) and the very low initial cost of the whole outfit, when an induction coil and electrolytic interrupter are used. These factors ought also, of course, to be considered in connexion with any standards of comparison that might be adopted. The cost is particularly important, because the price of apparatus is, unfortunately, a serious and sometimes crippling consideration with research workers in general.

The Cool-Flame and Two-Stage Ignition Systems in Ether-Air Mixtures at Room Temperature

The normal and cool-flame systems in diethyl ether-air etc. mixtures have been defined by means of diagrams showing the influence of pressure on their respective ranges of inflammability¹. Whereas the normal flame range centres upon approximately the theoretical mixture or that capable of developing the highest flame temperature and consequent flame speed, the cool-flame range appears to centre upon the mixture giving rise to the fastest reaction in slow combustion. High-tension sparks are employed for igniting the normal flames, but a suitably heated element must be used for the cool flames. If the experimental pressures in the cool-flame range be increased, pressure-composition limits may also be defined for the initiation of a second-stage 'blue' flame in the cool-flame products, this arises from the autogenous decomposition of peroxidic material formed in these products. This two-stage phenomenon is identical with that occurring in media *spontaneously* ignited at suitable temperatures and pressures², the essential difference being that with artificial ignition in cold media, the limiting pressures are much higher.

Hitherto it has not been possible with cold media to identify the cool-flame range within the normal flame range, for attempted ignition of cool flames by the means stated has invariably given rise to normal flames. An advance in this field has recently been made in that it is now possible completely to establish the cool-flame system (see graph), this was achieved in the first instance by allowing a cool flame initiated in a combustible-rich mixture located in one section of a 1.5 cm tube to pass into a mixture of composition within the normal flame range located in another section, connexion being effected by means of a uniform-bore tap. Similar observations have also been made with higher hydrocarbons and other suitable combustibles, and later the procedure became simplified when it was found possible successfully to employ a specially designed igniting source at rigidly controlled temperature. The importance of these observations may be appreciated by the statement that under suitable pressure conditions it is possible for a cool flame to travel quiescently through even a *theoretical* combustible air-oxygen mixture which, if subjected to a spark or other usual igniting source, would give rise to an explosion shattering the containing vessel. At higher pressures (Fig 1) the two-stage ignition mechanism occurs, giving rise in such a mixture to an explosion of great violence and of the type enhanced by shock waves. Indeed, there is strong evidence that under the conditions arising in internal combustion engines this two-stage ignition mechanism is, in fact, that responsible for 'knock'.

These observations throw light on the kinetics of the processes concerned, they may also be of significance when considering possible sources of ignition of inflammable vapour-air media in industries where solvents are employed, or possibly in operating theatres in hospitals. For it is possible for a cool flame initiated by a low-temperature source in a rich mixture (for example, ether vapour near a floor) to pass unobserved for some distance until, on pass-

ing into a mixture of higher oxygen content (for example, ether vapour more remote from a floor), an explosion of violence might occur.

The investigations referred to form part of a larger programme assisted by the Department of Scientific and Industrial Research.

Particle Shape

In the chemical literature it is customary for crystalline substances to be characterized as forming needles or plates. It is interesting to note that this concept of acicularity can be given a precise quantitative meaning and applied to any regular solid figure of which the three principal dimensions are known, and may be extended to cover the general form of irregular figures. In the present instance, rectangular solids are considered for the sake of simplicity, and the three dimensions denoted as a , b , c , where $a \geq b \geq c$.

Psychological tests have shown that a figure is instinctively considered to be acicular if a is greater than b or c , and tabular if a is less than b or c . If a equals b or c , no decision can be obtained as to whether the body is to be considered acicular or tabular. This criterion, related as it is to ordinary experience, is therefore considered to be the most satisfactory to adopt, and we define a quantity called the 'acicularity coefficient' as

$$\text{acicularity coefficient} = \frac{a}{b} - \frac{b}{c}$$

Bodies thus have an acicularity coefficient greater than unity if needle-shaped, and less than unity if tabular.

In the accompanying diagram the acicularity coefficient is constant in any vertical column. Another parameter is therefore required in order to specify uniquely any given shape. This is provided by a/b or b/c , whichever is the smaller. For this parameter we propose the name of 'isoproportionality coefficient', as it specifies the figure in the central column of the diagram which may be considered to be the parent figure of the corresponding horizontal row, just as the cube is the parent figure of the square prisms.

The correct method of applying these concepts statistically to a collection of particles is indicated as follows. If the particles have no inherent tendency to a needle- or plate-like form, it follows that those with an acicularity coefficient of n and $1/n$ will occur with the same frequency, and hence, for any one value of the isoproportionality coefficient, the sum of the values of $a \cdot b$, and the sum of the values of $b \cdot c$ will be equal, that is

$$\overline{a \cdot b} - \overline{b \cdot c} = 1.$$

Any inherent tendency to needle- or plate-like form will modify this value accordingly, and we therefore define a quantity, the acicularity factor, as

$$\text{acicularity factor} = \overline{a \cdot b} - \overline{b \cdot c},$$

which is equal to the acicularity coefficient of a mean particle averaged in the special way involved in this definition. This derivation is applicable severally to groups of particles having every possible value of the isoproportionality coefficient, and therefore is applicable to any group of particles whatever, providing it be sufficiently large.

For statistical use, the isoproportionality coefficient will similarly give place to the isoproportionality factor, defined as

$$\text{isoproportionality factor} = \overline{x \cdot y},$$

where $x \cdot y$ is the smaller of the two ratios $a : b, b : c$, for each individual particle.

Boron and Strontium in New Zealand Coal Ashes

ATTENTION has been directed by V M Goldschmidt¹ to the occurrence of minor elements in coal ashes. During the complete analysis of ash of Waikato coal examined in connexion with clinkering troubles, Mr F. T. Seelye, chief chemist at the Dominion Laboratory, New Zealand, noted a high boron content. The Coal Survey Division then undertook an examination to determine the distribution of boron in New Zealand coal ashes. Boron was present in highest amount in Waikato coals, but was also present in smaller percentages in all New Zealand coals.

The accompanying table sets out the maximum and average percentages of boron in each coalfield. The factor of enrichment of boron in coal ashes has been worked out as in Goldschmidt's paper, by comparing the percentage of boron in coal ash with the percentage of boron in the earth's crust taken as 0.0003.

Another element occurring in unusual amounts is strontium. Strontium has been determined by a spectrographic method similar to that described by Wilson and Fieldes², but modified by them to permit the determination of strontium directly on the ash, without separation of lime and strontia (unpublished method).

Strontium was found to be much higher than is usual in rocks, amounting to 0.3 per cent strontium

Coalfield	Class of coal	Maximum % boron	Average % boron	Factors of enrichment Maxi- Aver- mum age	
North					
Auckland	Sub-bituminous	0.21	0.21	700	700
Waikato	"	1.51	1.09	5,000	3,000
Taranaki	"	0.73	0.58	2,400	1,900
Westport	Bituminous	0.29	0.29	1,000	1,000
Reefton	Sub-bituminous	0.86	0.86	3,000	3,000
Greymouth	Bituminous	0.15	0.07	500	250
Otago	Lignite	0.14	0.11	500	400
Kaitangata	Sub-bituminous	0.44	0.39	1,500	1,300
Southland	"	0.24	0.18	800	600
Chatham Islands	Peat	0.10	0.10	300	300
Goldschmidt's figure for coalashes rich in boron		0.30	0.06	1,000	200

oxide in several Waikato coal ashes. In ash from Mangapehi, an area south of the Waikato coalfield, the strontium content was found to be far above the amount usually determined spectrographically. A chemical determination revealed 1.3 per cent strontium oxide. The percentage was then confirmed by modifying the spectrographic method.

Further information is necessary before any conclusion as to the reason for these high concentrations can be put forward. It is significant that boron and strontium are relatively high in sea-water, and the high content of both may be connected in some way with contact of the coal measures with the sea. It must also be noted that the coals high in these constituents occur in hot spring or volcanic areas.

Red Shift in the Anagalactic Nebulae

A PHOTON $h\nu$ emitted by a distant nebula toward our galaxy possesses a mass

$$\mu = \frac{h\nu}{c^2} \quad \dots \quad (1)$$

and the equation for its energy is

$$h\nu = \mu c^2 \quad \dots \quad (2)$$

The mass μ of the photon is acted upon by the gravitational field of our galaxy, whatever this field may be. Newtonian, LeSagien¹, or the relativistic curvature of space caused by the mass of the galaxy.

The law of gravitation requires that any mass in the field of our galaxy must be accelerated toward it. Therefore, using the inverse square law for falling bodies, the energy of the photon from the nebula we observe should be

$$h\nu = \mu \left[\sqrt{c^2 + k \left(1 - \frac{R}{A}\right)} \right]^2 = \mu \left[c^2 + k \left(1 - \frac{R}{A}\right) \right], \quad (3)$$

where $k = \frac{2GM}{R}$, R is radius of our galaxy (assuming

it to be spherical as a first approximation), A is the distance from the galaxy to the nebula, M is mass of our galaxy, and G is the gravitational constant. However, according to the principle of relativity, no mass can acquire a velocity greater than c , the velocity of light *in vacuo*. Consequently, in order to preserve the law of gravitation, together with the conservation of energy involved, and to agree with the principle of relativity the following equation must be satisfied

$$h\nu - \mu k \left(1 - \frac{R}{A}\right) = \mu c^2, \quad (4)$$

or, substituting μ by its value from (1), we have

$$h\nu \left[1 - \frac{k}{c^2} \left(1 - \frac{R}{A}\right)\right] = \mu c^2. \quad (5)$$

On the right-hand side of this equation c is constant and, therefore, μ cannot vary, which makes μc^2 constant. On the left-hand side of the equation, h is Planck's constant. Therefore, in order to satisfy equation (2), ν which we observe in the photon coming from the nebula, and which is on the left-hand side of equation (2), must have a value different from ν which the photon possessed at the moment of emission, and become a variable frequency ν^1 , a function of the argument A . Equating (2) with (5), we have

$$h\nu^1 = h\nu \left[1 - \frac{k}{c^2} \left(1 - \frac{R}{A}\right)\right]. \quad (6)$$

This equation shows that under an acceleration by the field of gravitation a photon keeps its velocity constant by adjusting its frequency so as to compensate for the variation due to the acceleration.

The red shift of the 'expanding universe' is an immediate corollary of equation (6), as the observed wave-length λ^1 is $1/\nu^1$, and, therefore, increases with the distance A .

It seems that the idea presented is worth discussion, I should be much interested in any comments on the subject.

Surface Tension of Solutions

In a recent paper¹, Wales discusses the approximate relations for the surface tension of regular solutions. He concludes that the surface tension is linearly or quadratically related for ideal and regular solutions respectively to the molar volume fractions of the components.

Two facts, however, limit the applicability of these relations: (1) The omission to take into account the adsorption at the surface which is responsible for the disagreement between the relations obtained and the Gibbs equation for the surface tension. (2) The neglect of the orientation of molecules at the surface.

In a theory I have recently developed² both those effects are accounted for in terms of the monolayer, while the derived relations for the surface tension agree perfectly with the Gibbs equation and cover the whole range of concentrations. At close values of the surface tension, relations analogous to those derived by Wells are obtained, while the surface tension for ideal solutions is linearly related to the surface molar fraction, which indicates the area occupied by molecules of the given species in the monolayer. An inspection of the benzene-carbon disulphide system, discussed by Wells, shows the carbon disulphide molecule to be oriented perpendicular to the surface.

A paper devoted to the statistical treatment of regular solutions and, in particular, to the analysis of the benzene-carbon disulphide system was ready in February 1944 and is to appear shortly in *Acta Physicochimica USSR*.

Plant-Growth Substances and *Penicillium notatum*

It was considered of interest to study the effect of plant-growth substances on the production of penicillin by the mould *P. notatum*. Several experiments have been carried out using indole-3-acetic acid and α -naphthalene acetic acid. The study has included the use of various media with the Squibb strain of *P. notatum* (American Type Culture Collection). Heavy spore inocula were added to two quart bottles (flat type) containing about 300 ml. of the medium. The bottles after inoculation were kept at 23-24°C and 80 per cent humidity. As might be expected, marked stimulatory effects of the growth-substances were found only in the cases of the simple media, such as Czapek-Dox with added brown sugar. The experiments reported refer to penicillin production in the latter medium with 4 per cent brown sugar. Addition of either of these growth-substances at the concentration of 1 part in 30,000 had no effect in a mineral and corn-steep (6 per cent) medium. The titres obtained with the simple medium plus the growth substances are higher than have previously been reported for this medium alone. The practical value of the findings is limited, however, for much higher titres are the rule with the corn-steep media. This work suggests that a part of the good results got with the corn-steep may be ascribed to its containing plant-growth stimulants; but this point has not been checked.

The results of repeated tests have been somewhat erratic because of the variation in bottles inoculated under identical conditions. Almost without exception, however, the bottles containing the growth substances have developed mature mould mats in somewhat shorter times, and the titres of penicillin (both at the same time and at comparable stages during the development of the mat) have been higher than in controls. It is not known whether this is due to a faster growth or to a greater total growth of the mould, or to an increased secretion of penicillin. It is thought that faster growth of the mat will account for the findings, for, of course, the quicker the peak concentration of penicillin is reached, the higher it will be, there being less time for the decomposition of the accumulating penicillin.

A single, complete experiment is given in the table, the titres representing the best bottle of a triplicate group. Repeated experiments gave the same indications, but not usually the same figures.

EFFECT OF PLANT-GROWTH SUBSTANCES ON PENICILLIN TITRES FROM *P. notatum* ON A SIMPLE MEDIUM

Medium	Days after inoculation	Penicillin (Florey units per ml)
Control	6	30
Indole acetic acid, 1 in 10,000	6	50
Naphthalene acetic acid, 1 in 10,000	6	25
Control	7	35
Indole acetic acid, 1 in 10,000	7	50
" 1 in 100,000	7	35
Naphthalene acetic acid, 1 in 10,000	7	40
" 1 in 100,000	7	50
Control	11	28
Indole acetic acid, 1 in 10,000	11	50
" 1 in 100,000	11	30
Naphthalene acetic acid, 1 in 10,000	11	30
" 1 in 100,000	11	45

It is thus seen that indole acetic acid at a concentration of 1 part in 10,000 gives the quickest high titre of penicillin, whereas it is not so active at 1 to 100,000. Naphthalene acetic acid is more active at 1 part in 100,000, giving a titre peak in seven days. The two concentrations mentioned were the only ones studied, and it is likely that the optimal one has not been chosen. Work along these lines is being continued.

Ripening of the Onion Bulb and Infection by *Botrytis* Species

THE first sign of normal ripening in the onion plant, it is supposed, consists of a local collapse at the neck, resulting in the leaf blades falling over on to the ground while several of them are still green and turgid, this can occur with plentiful soil moisture^{1,2}, though hastened by drought, and has been attributed (*loc cit*) to a softening of the tissues of the neck. The true explanation would appear, however, to be purely mechanical, and connected with the mode of development of the onion bulb. In the absence of bulbing, as in an onion plant growing in short days, new leaves emerge at regular intervals. Each leaf consists of a thin-walled hollow cylindrical leaf base surmounted by a more or less cylindrical 'blade' which is at first solid but later develops a lysigenous cavity. At the junction of the leaf base with the leaf blade a pore is found, through which the next younger leaf emerges. The neck of the actively growing onion plant thus consists of a number of very thin concentric leaf bases enclosing a practically solid core of growing leaf blades. The outermost leaf bases are dead and papery, but even the living ones have little inherent rigidity, the solid core is formed by the blade or blades of the one or two leaves next emerging. When, under the stimulus of long days, bulb development occurs, leaf emergence ceases immediately or soon according

to conditions^{2,3} and the three leaf initials next due for emergence become instead swollen bulb scales with practically no leaf blade³. The result is that after the blade of the last leaf has emerged there are no more to provide the solid core of the neck, which thus becomes a thin-walled hollow tube. This soon buckles and collapses under the weight of the green leaf blades, especially in wind or drought. Experiment has shown that removal of the central core very greatly reduces the resistance of the neck to buckling.

The common horticultural practice of bending onion plants over at the neck to hasten ripening thus appears groundless. If bulbing has not proceeded far enough to stop leaf emergence, the practice can only result in breaking or bruising the next emerging leaf blade, while if leaf emergence has ceased the neck will of itself collapse very soon, though there seems no obvious reason why this should either hasten the drying of the leaf blades or the onset of dormancy, which together accompany ripening.

Before bulbing occurs, the pore at the junction of leaf base and blade is from the earliest developmental stages of the leaf initial blocked by the tip of the subsequent leaf³. The last leaf to emerge after bulb development, however, has an open pore, since the next leaf initial forms a swollen bulb scale the blade of which fails to elongate. If, therefore, this last leaf emerges fully before collapse of the neck occurs, the onion plant has then a more or less open pore communicating directly by the hollow neck with the interior of the bulb. Since we have in a number of cases found the swollen bulb scales infected (apparently with *Botrytis* spp.) while the surrounding swollen leaf bases³ have appeared healthy, it would seem that this probably provides one of the modes of infection of the onion bulb by spores of *Botrytis* spp., which constitutes one of the main problems of economic importance connected with onion culture and storage in Great Britain. Another likely path of infection is via the pores of the other (older) leaves, since these sag open as the leaves wither and thus provide pockets for the lodgment of air-borne spores and probably fairly high humidities for their germination. This would presumably lead in the first instance to infection of the swollen leaf bases rather than of the swollen bulb scales, and this is the most frequently observed condition in the early stages of *Botrytis* 'neck rot'. That infection does in fact occur via these pores is indicated by our observations of the occurrence of 'neck rot' in the greenhouse, where the plants are somewhat etiolated and the necks very much longer than under field conditions. Here the tissues of the leaf bases are killed high up on the neck near the pores, and even the whole neck rotted through at that level, before the bulb shows any obvious infection.

The above considerations provide yet another example of the importance of the cessation of leaf emergence with bulb development in accounting for the behaviour of the onion plant².

Sulphonamides and American Foul Brood Disease of Bees

AN editorial note in a recent issue of *Gleanings in Bee Culture* (72, 493; 1944) reports on the use of sulphathiazole in the treatment of American foul brood disease of bees by Prof. Haseman, University of Missouri, Columbia. Sugar syrup containing sulphathiazole fed to the bees enabled them to raise healthy brood in combs containing the scales of larvæ which had died of the disease.

In 1943, Mr. C. A. Ekins, of Brookwood Hospital, Surrey, sent to this Department an account of some experiments he had been carrying out since May of that year, in which sulphapyridine was being used in the treatment of five colonies of bees affected with American foul brood. He continued his experiments until July 1943 (with further treatment as a preventative measure in the following spring), since which date, he reports, there has been no recurrence of the disease. No evidence of disease was found when the colonies were examined in May 1944 by the local officer appointed for the inspection of apiaries under the Foul Brood Disease of Bees Order.

Following upon Mr. Ekins' claims of complete success with his treatment, and after consultation with him, it was decided to carry out a trial of sulphapyridine in the experimental disease apiary at Rothamsted. Accordingly, in June 1944, two colonies of bees of approximately equal strength, and headed by hybrid queens of the same age, were infected with American foul brood by feeding them a suspension of the spores of *Bacillus larvæ* in sugar syrup. The disease was allowed to run its course in both colonies until August 3, when one of them was fed 600 ml. of sugar syrup containing 3 gm. of soluble sulphapyridine. This treatment was repeated at weekly intervals, four doses being given in all. The other colony was fed plain syrup in equal quantities on the same dates. On September 8 the bees in both colonies were killed and the combs then examined. No major honey flow occurred during the period of treatment.

There was a marked difference between the two sets of combs. In those from the treated colony all the recent brood appeared healthy, though somewhat scattered and irregular in arrangement. No larvæ in the early or ropy stage of the disease were found, with the exception of two individuals situated on a comb remote from the three combs forming the actual brood-nest. Scales, the formation of which normally takes about three weeks from the death of the larva, were, however, present in eight out of the eleven combs in the hive. In the combs from the untreated colony many ropy larvæ were present, along with others showing the progressive stages leading to the formation of the scale.

It would appear, therefore, that during the course of the treatment the progress of the disease within the colony had been arrested, and that only healthy brood was being reared in combs where the disease had previously been established. The test was a severe one owing to the length of time which elapsed between infection and the beginning of the treatment; it was purposely not carried to its ultimate conclusion because of the lateness of the season and because of the danger of robbing by bees from other hives nearby.

It should be noted that the conditions of the experiment were not identical with those of the ex-

periments carried out by Mr. Ekins, who combined manipulative methods with the sulphapyridine treatment, and a complete elimination of the disease, as claimed by Mr. Ekins with his methods, was not obtained. The result does, however, justify the planning of future tests on a larger scale.

Phagocytosis and Storage of Trypan Blue in the Appendix of the Rabbit

THE observations of Baker and Enticknap¹ substantiate the claim of Bizzozero and Ruffer (cited by McEwan²) that an active phagocytosis occurs in the appendix of the rabbit, the agents concerned being large mononuclear cells present in the lymph follicles and lymph papillæ of the submucosa. The following observations, made on the appendices of vitally stained adult rabbits throw additional light on this process.

The dye, trypan blue, was administered subcutaneously in a 2 per cent solution in distilled water and the animals were killed at various intervals after stopping the injection. The amounts of the dye used, the frequency of the injections and the times when the animals were killed are given in the accompanying table.

Rabbit	Daily dose of trypan blue (c.c.)	No. of injections	Time between last injection and killing
1	2.5	1	12 hr.
2	2.5	2	2 days
3	2.5	2	10 days
4	5.0	2	2 days
5	5.0	2	10 days
6	7.0	2	2 days
7	7.0	2	5 days
8	10.0	2	2 days
9	10.0	2	10 days

Following the administration of trypan blue in moderate concentration (R 1, R 2 and R 3) particular segregation of dye particles occurred in the cytoplasm of cells in the serous coat, in reticulum cells surrounding the follicles and in certain cells of the mucosa. The dye-containing cells in the serosal coat were frankly macrophagic. Those in the peri-follicular tissue were rather smaller, but the majority of them exhibited the staining characters of macrophages. A few showed an early rosette arrangement of the dye particles often seen in monocytes. These cells were abundant in the region of the peripheral lymph sinus of the follicles, and at many sites appeared to project into its lumen. Cells of similar size and with identical staining characters occurred near the lymph channels in the mucosa. At other situations in this zone, notably around encysted sporozoa (abundant in larger or smaller groups), macrophages with a more bulky cytoplasm were electively stained, and the appearances suggested that many of them play an important part in the defence reaction of the mucosal tissues towards these parasites. The follicular lymphocytes were not affected by the dye; but numerous large moribund cells and disintegrating cell debris in the centre, and to a less extent at the periphery of the follicles, were diffusely stained (see photo.).

The administration of the dye in larger amounts (R 4, R 5, R 6 and R 7) produced a marked increase in the number of dye-containing cells in the peri-follicular zone and around the mucosal lymph

LONGITUDINAL SECTION OF RABBIT APPENDIX (R.5) SHOWING DIFFUSELY STAINED MORIBUND CELLS IN THE CENTRAL AND PERIPHERAL REGIONS OF A LYMPH PAPILLA. MASSON'S PONCEAU-ACID FUCHSIN, $\times 120$.

1, Epithelium of papilla; 2, reticulum in deeper part of mucosa containing lymph channels and blood vessels; 3, mucosal lining; 4, lumen of appendix.

channels. In R 5 and R 7, the animals of this series which were killed at later periods, there was, as compared with R 4 and R 6, an appreciable reduction in the number of the stained cells associated with the lymph channels in the perifollicular and mucosal regions. This reduction appeared to be due to a desquamation or migration of the cells into the lymph follicles, where the appearances indicated that some were phagocytosed among the central cells of this region. R 5 and R 7 also exhibited fine dye inclusions in the cytoplasmic processes of the perifollicular reticulum fibres, and in many situations dye particles were observed in elongated cells lying adjacent to the endothelium of the blood vessels. In all animals of this series the intensity of the stained elements around encysted sporozoa deepened.

In more intensely stained animals (R 8 and R 9), cells of macrophagic character containing fine dye particles appeared in increasing numbers within the lymph follicles. Many of these cells had presumably migrated into this situation from extrafollicular sites, but there was evidence in R 9 that dye particles had been segregated by certain follicular cells—possibly lymphocytes which had developed in a macrophagic direction as a defence reaction to the increased stimulation.

It was noted that the central parts of most of the lymph follicles contained many large mononuclear cells having all the morphological characters of macrophages but which were entirely unaffected by the dye. These cells are probably identical with the phagocytic elements (macrophages) recorded by Baker and Enticknap¹. It may be that the relatively poor blood supply to the regions containing these cells accounts in part for their inability to segregate dye particles. On the other hand, it is possible that other activities peculiar to their situation, for example, phagocytic, incapacitate them from taking up other substances presented to them, as Cappell² has suggested in the case of similar cells found in lymph glands.

The above observations confirm the presence of numerous phagocytic cells within the lymph follicles of the rabbit appendix, but the majority of these are not readily stainable by means of trypan blue administered by the subcutaneous route. A renewal of

the elements concerned in this process from follicular cells is indicated, and the proximity of diffusely stained moribund cells and of extracellular dye particles to the epithelium covering the lymph papilla suggests a process of elimination at this site. It would appear that phagocytosis occurs mainly within the follicles. In this situation a true germinal or lymphoblastic core is not well established, and Crabb and Kelsal³, following the suggestion of Ehrlich⁴, refer to this tissue as "lymphoid" rather than lymphatic. Latta⁵ and West⁶ regard the central part of the follicle as a region of cellular degeneration rather than one of proliferation. Latta⁵ recorded a decrease in the number of lymphocytes and the presence of numerous moribund cells in the central parts of the follicles, and stated that this results from a local inanition due to the poor blood supply of these regions. Crabb and Kelsal³ observed "clusters of moribund large lymphocytes resembling the 'ghost cells' of Todd and Sanford"⁷ towards the periphery as well as in the central parts of the follicles, and recognized the possibility of the former site as being closely related to elimination.

While the levels of vital staining employed in the above experiments produced no obvious general upset in the animals, it is important that care should be exercised in the interpretation of results, for in this, as in other situations, the dye itself is obviously capable of producing proliferative changes in susceptible elements.

Colour-blindness in Left Eye following an Accident

A MAN of fifty years of age, knocked down by a bus in 1942, sustained fractures of facial bones on the left side, was unconscious for ten days, saw double for six months, had electrical treatment and recovered. There were no brain injuries, but severe facial paralysis on the left side. In 1944 he was brought by a friend, Mr. W. Macaulay, and proved an accurate and consistent observer. The left eye was his better eye before the accident.

Prof. Arnold Lowenstein kindly examined his eyes, with the following results: R. fissure 12 mm., L. 10 mm.; L. eyelids unable to close completely; no disturbance of eye-movements; L. cornea hypoesensitive; R. pupil 4 mm., L. 3.5 mm., both pupils gave immediate reaction to light, but L. reaction inconsiderable; convergence reaction to 2.5 mm. in both pupils. R. eye: fundus myopicus with inferior conus and optic colaboma between 5 and 7 o'clock; disk of pinkish colour. L. eye: 1-1.5 d. myopia; disk sharply defined, of a bluish-white colour; vessels well filled and no sheathing; atrophic excavation, small area of pigmentation round disk; otherwise fundus normal.

Usual colour names		Violet	Blue	Blue-green	Green	Yellow-green	Yellow	Orange	Red
Names used by subject	R eye	Light blue	Blue	Blue-green	Green	Yellow	Yellow	R yellow	Red
	L eye	Grey	Grey		Green		Grey	Grey	Grey

Visual acuity was corrected as follows, without correcting astigmatism R eye to 4/36 with -4.0 d, L eye to 4/18 with -1.0 d. With these corrections he did the Ishihara test (25 plates) R eye, all correct, L eye, none legible whatever.

Perimeter test R eye normal with 1 cm disks of red, yellow, green and blue L eye normal with 5 cm disks of red, yellow and blue, but 1 cm disk of green sufficed. No central scotoma, but red was less saturated in central area, L eye.

Independently of Prof Lowenstein, a colorimeter test showed that the right eye was normal but had a slight weakness in red, but the left eye was normal only for green, since red, yellow and blue were equated with greys of normally equivalent brightness.

After six to seven weeks, when the other tests were done, the right eye gave the same result, but the left eye had improved to about 1/25 normal thresholds for red, yellow and blue. This corresponded to the perimeter test, in which the left eye had 1/25 normal sensitivity to these colours.

The Edridge-Green Beads and the Holmgren Wools confirmed that colour vision was normal with the right eye, while green was the only colour seen clearly with the left eye. The colour perception spectrometer gave the result shown in the accompanying table.

The subject knew that he could see only green clearly with the left eye, and identified it as the colour he called green with the right eye.

The bearing of this case on theories of colour vision is important. It would be expected that primary colours, on any theory, might be lost independently of each other through shock or injury, and/or that colours lower in the scale of evolution, on any theory, would be retained longer after injury or shock, while those more recently evolved would recover last.

*Willmer's 2-colour theory*¹ Red and violet are the only primaries. Loss of these would give total blindness, partial loss would give darkening of both ends of spectrum and proportional loss of green. The theory is not supported.

Young-Helmholtz 3-colour theory Green might be retained while red and violet-blue were lost, but both ends of spectrum would be extremely darkened.

*Walls's modified 3-colour theory*². Weakness of colour vision is due to shifting of sensitivity curves so that they overlap. Red and blue-violet might be lost, but both ends of spectrum would be darkened, and, since all three sensitivity curves would now overlap in the middle, 'green' would be greatly brightened and would be wholly replaced by grey. No support is given to either form of the Helmholtz theory.

Ladd-Franklin's evolutionary theory If yellow and blue are lost, then both red and green must be lost, too, since they evolved later and depend on the integrity of the blue and yellow sensations.

Edridge-Green's theory. The dichromatic form of colour vision discriminates the ends of the spectrum as yellow and blue, and evolves out of monochromatic vision, in which only grey is seen. It develops into trichromatic colour vision, in which green is added between yellow and blue. In the case reported green

is distinguished from the ends of the spectrum, which are both grey, and it lends no support to the theory.

Hering's 4-colour theory Blue and yellow, and/or red and green, could be lost while the corresponding brightness sensations remained. Green could be retained, as in the case reported, while red, yellow and blue were lost, if the dissimilative process of the red-green pair became checked at the neutral point and could not proceed towards red.

*Houstoun's modification of Hering's theory*³ The changes from red to green and from yellow to blue depend on the proportions of red to green and of yellow to blue responses. Yellow and blue light might both excite yellow and blue responses equally frequently, giving yellow-blue blindness. Green light might still excite the normal preponderance of green over red responses, and red light excite both red and green responses equally often, so that the normal change over failed to proceed further than the neutral point. This would explain the case described.

In general, it may be concluded that the case described strongly negates all colour theories except Hering's, while Houstoun's modification of this theory is the most fully supported.

Cannibalism in *Aurelia*

PLANULÆ of *Aurelia* were washed out of the brooding pits of the mother medusa and allowed to settle down in small dishes about 35 mm wide and about 7 mm high (very suitable for microscopic investigation). These dishes were gently placed in large basins (capacity about two litres) and left undisturbed until the larvæ got hold of their substratum. This usually took about 36 hours, after which time the basins were placed under running sea water, thus giving the larvæ access to their natural food. However, it was observed that certain scyphistomæ attacked their neighbours. The 'aggressor' would extend its body until the mouth would reach the 'victim', then the mouth would be widened so as to enclose the greater part of the victim, which would resist and stick firmly to the substratum. A struggle would take place, but at last the whole body of the victim would be taken in the coelenteron of the aggressor. The scyphistomæ usually bud off a number of individuals which separate and settle down round the mother-scyphistomæ, but cannibalism has not been observed among members of such a group.

RESEARCH ITEMS

Secondary Sexual Characters in Beetles

THE great development of horn-like outgrowths in male Dynastid beetles is a conspicuous secondary sexual character. What these horns are used for has long attracted attention and excited speculation. William Beebe (*Zoologica*, 29, Aug. 1944) records observations made in the New York Zoological Society's Laboratory at Caripito, Venezuela, on the elephant beetles *Megasoma elephas* and *Strategus aloeus*. In both these species he finds that the males use their cephalic and thoracic horns for fighting with each other. The initial stimulus appears to be the advent of the rainy season. The technique of fighting seems to be the same for both species: first an effort to unbalance the opponent by tripping, and then by ventral attack with the anterior horn so as to throw him on his back. It is interesting to note that Charles Darwin, in the first edition of "The Descent of Man", claimed that the most obvious conjecture is that these horns are used by the males for fighting together. But since they had never been observed to fight, he came to the conclusion that they were acquired as ornaments. Eight years afterwards, A. R. Wallace, in "Tropical Nature", expressed the view that these horns may be protective. Their presence, he says, would render it very difficult for the large-mouthed goatsuckers and other nocturnal birds to swallow the beetles. It is therefore noteworthy that Mr. Beebe's observations appear to settle this disputed point, and are supported by a very convincing series of successive photographs taken of actual combats.

Intracellular Symbiosis and Vitamin Requirements of Insects

MANY insects contain symbiotic micro-organisms, usually bacteria or yeasts. The organisms are intracellular and are housed in special organs called mycetoms. One function of such organisms seems to be the synthesis of certain vitamins normally required for the nutrition of the insect. M. Blewett and G. Fraenkel (*Proc. Roy. Soc. B*, 132, 212, 1944) have studied this question in the case of the larvæ of two beetles, *Lasioderma serricorne* and *Sitotroga panicea*. It is possible to sterilize the eggs before hatching and so obtain larvæ free from symbionts (sterile larvæ). Such sterile larvæ fail to grow if the diet is deficient in any one of the following components of the vitamin B complex: thiamin, riboflavin, nicotinic acid, pyridoxin, pantothenic acid. On a diet rich in vitamin B (wholemeal flour and yeast) both sterile and normal larvæ grew equally well, while on a diet deficient in vitamin B (white flour) the sterile larvæ did not grow so well as the normal ones. It was concluded that, in the case of these two larvæ, the normal symbionts could synthesize the various components of the vitamin B complex in amounts sufficient to meet the normal growth requirements of the larva (see also *Nature*, 152, 506, 1943).

Nervous Control of Intestinal Function in the Earthworm

N. MILLOTT (*Proc. Roy. Soc. B*, 131, 271, 1943) has shown that the intestine of *Lumbricus*, while possessing an intrinsic nervous system of its own, is also supplied by nerves from the central nervous system. There are two such extrinsic systems of nerves, one inhibitory and one excitatory to the intestinal muscle, and the condition is thus parallel to that obtaining in the vertebrates. Further (*Proc.*

Roy. Soc. B, 132, 200, 1944), Millett has shown that stimulation of the extrinsic nerve supply causes the secretion of protease by the glandular cells of the intestinal epithelium. The glandular cells showed the usual histological changes associated with secretion, and an increase of protease was demonstrated in the intestinal fluid. The probable course of the nerve fibres was mapped out by the usual methods of electrical exploration.

Rubidium in Algae and Freshwater Plants

THE presence of rubidium as a 'trace element' in certain plants has been recognized since 1862, when Grandea identified it in the ash of beet and succeeded in extracting no less than 400 gm. of pure rubidium chloride from that source. Rubidium has also been reported in various other plants and plant organs (for example, tobacco leaves) and is usually derived by the plant from traces present in the soil. T. F. Borovick-Romanova, in a paper on the content of rubidium in plants (*C. R. Acad. Sci. U. S. S. R.*, 43, 163, 1944), gives an account of the quantitative spectroscopic examination of the ash from fifteen different seaweeds (*Laminariales*, *Fucales*, *Rhodymeniales* and *Charales*) and from fourteen higher water-plants. The results, which are tabulated to show the percentage of metal in the ash and in the live plant, and also the rubidium-potassium ratio, were checked by comparison with lines produced by addition of definite quantities of barium salts. The rubidium content of the seaweeds is more than ten times that of the sea water in which they grew (2×10^{-5} per cent), while in the freshwater plants it is almost a thousand times that of the medium in which they were found. The rubidium-potassium ratio is higher in the *Laminariales* than in the *Fucales*, the average rubidium content being about 1 per cent of the ash, or 0.005 per cent of the live weight. Among the freshwater plants examined, the water-lilies showed the highest rubidium content, with 6.7 per cent of the total ash from the roots of *Nuphar luteum* (or 0.0052 per cent of the fresh weight). The plants had been collected between 1933 and 1938 from such widely separated parts as the Barents Sea, the Pacific Ocean, the Caspian Sea and the Staroselje reserve of the Ukrainian Academy. Their examination occupied the intervening years and follows a study of the distribution of rubidium in sea waters. It is a part of a survey of the occurrence of rubidium in the biosphere.

Boron in Horticulture

SINCE the first demonstration that boron is an essential element in plant nutrition, boron deficiency in a great variety of crop plants growing in the field has been recorded. Correction of boron deficiency by the use of dressings of borax is not always a straightforward matter, as in many cases the limits of boron tolerance are narrow, and A. S. Heimicke, W. Reuther and S. C. Cam (*Proc. Amer. Soc. Hort. Sci.*, 40, 31, 1942) suggest that the application of borax even to a boron-deficient soil may induce separation of apple fruits from the trees, although this may be the result of an acceleration of fruit development as found by L. P. Batjer and M. H. Haller (*ibid.*, 40, 29, 1942). Usual dressings of borax are of the order of 10 lb. per acre, this amount is sufficient to control boron deficiency in the field in cauliflower, radish, beet and swede (R. H. White-Stevens, *ibid.*, 39, 367, 1941), while half this amount will increase the yield of potatoes and peas on

soils deficient in boron, but where the deficiency is not sufficiently acute for characteristic boron deficiency symptoms to develop. Twenty pounds of borax per acre may be harmful to spinach and carrots, and it is therefore surprising to find that indications of borax injury to eighteen-year-old apple trees did not develop until the applications of borax to the soil had reached the level of 10 lb per tree (L P Latimer and A P Percival, *ibid*, 43, 21, 1943), and these damaged trees showed complete recovery in the following year.

Spraying of Fruit Trees with Growth Substances

A E Hitchcock and P. W. Zimmerman (*Proc Amer. Soc Hort Sci.*, 42, 141, 1943) describe the effects of spraying different fruit trees during the summer with growth substance (potassium α -naphthyl acetate). Peach and plum especially and apple, pear and cherry, to a lesser extent, responded to the treatment by delaying the opening of fruit and flower buds in the following spring. In the same journal, P C. Marth (pp 620-628) describes how exposure of rose bushes during the winter to the vapour of naphthyl methyl acetate retards their shoot development. The magnitude of the response depends partly on the physiological condition of the bushes—'high starch' plants showing a greater retardation of shoot growth than 'low starch' ones. Of theoretical interest, these experiments have a practical bearing also as they offer with rose and fruit bushes a possible method of prolonging shoot dormancy and so escaping some of the damaging effects of spring frosts, and of extending the planting season.

Verticillium Wilt of the Tomato

WILT diseases of the tomato crop are widespread, and though a useful control can be effected by maintaining the temperature between 70° and 74° F, this is not always feasible. Soil factors which affect the pathogenicity of the fungus *Verticillium albo-atrum* have been investigated by F M Roberts (*Ann Appl Biol.*, 30, 4, 327, 1943). Attack by the fungus appears to depend to some extent upon lack of competition from other soil organisms. Inoculation of the ground immediately after steam sterilization gave nearly 90 per cent infection, as against 55 per cent in unsterilized soil. Sterilization thirty-two days before inoculation resulted in only 28 per cent infection. Nitrogenous manures favoured infection, phosphate had little effect, but a deficiency of potash also encouraged the parasite.

Thermodynamic Diagrams of the Atmosphere

CARMELO DI CORLETO has discussed, under the title "Comparación Entre Los Diagramas Termodinámicos De La Atmosfera, Mas Usados En Meteorología" (*Pub Fac Cien Fisicomat*, 3, No 1, Univ. Nac De La Plata), the work of various investigators on the subject of variations in mass of moist air, due to ascending and descending movements. Diagrams based on the work of Hertz (1884), of Neuhoﬀ (1900), and in more recent times of Kreitmeyer, Bjerknes, Stueve, Shaw, Refsdal and Lajtmán are supplied, and the basic assumptions regarding the various conditions, and the formulae derived from these, are briefly discussed. There is a certain amount of discrepancy in the views of different meteorologists on the results of their investigations, to which the author directs attention at the end of the paper. Criticisms

of some of the diagrams are referred to, and the views of Brunt, Rothé and Refsdal on the diagrams devised by Neuhoﬀ, Bjerknes and Shaw are quoted. Comparison of the different diagrams, made in the paper, leads to the view that the preference for any thermodynamic diagram over another is based solely on questions of convenience. Any one of them provides the reader with the conditions of the air so far as atmospheric stability is concerned.

A New Representation of the Types of Nuclear Forces

IN *Revista de la Facultad de Ciencias Fisicomatemáticas*, 3, No 29 (Instituto de Física, La Plata, Argentina), Mario Bunge has a paper with the title, "Una Nueva Representación De Los Tipos De Fuerzas Nucleares". In Section 1 he deals with the fundamental characteristics of the usual representations of nuclear forces and gives a brief outline of the theories of Gamow, Gurney and Condon, Heisenberg and others. Operators are then introduced which are formally identical with those employed in Dirac's theory of the relativistic electron, and these are able to supply an explanation of the four quantum states of the nucleon in non-relativistic approximation. By the employment of this new notation, explicit use of the isotopic spin is excluded, and it is synthesized with the ordinary spin in a single four-valent variable. The various scalar and non-relativistic potentials theoretically possible are formed by means of these new operators, and they are then applied to the problem of the deuteron. At the end of the paper there is a discussion on the advantages and the limits of the representation.

Hydrogen Bond and Diamagnetism

A CRITICAL analysis of the available data by S V Anantkrishnan and P S Varadachari (*Proc Indian Acad Sci*, 20 A, 128, 1944) shows that the contribution to diamagnetic property by the methylene group CH_2 is constant, $\chi_m = 11.69$. On this assumption, it is shown that hydrogen bonding leads to increased diamagnetism, with a susceptibility change of one unit per mol whenever structures of the type $\text{O}-\text{H} \cdots \text{O}=\text{A}$ are involved. A bifurcated hydrogen bond, as in iodic acid, apparently leads to an even larger value. The decrease of diamagnetism in water and alcohols on association is interpreted as due to an increase of the paramagnetic term associated with distortion. The interpretation of structures is considered in the paper.

Fatty Substances in Starch

CONSIDERABLE importance has been attached to the fatty constituents of starch, which interfere with the fractionation of starch and many properties of cereal starch pastes. Since the fat is not removed by a typical fat solvent such as ether or carbon tetrachloride, it has been supposed to be present in the form of esters with starch, but the adsorption of palmitic acid by starch is typical and throws doubt on this chemical theory. R L Whistler and G E Hilbert (*J Amer. Chem Soc*, 66, 1721, 1944) find that the fat is easily removed from disintegrated corn starch granules by methanol, although it is difficult to extract from the intact granules. At the same time the phosphorus content of the starch is appreciably reduced, and the nitrogen content is affected to a lesser degree. All the fatty matter in corn starch (about 1 per cent) is apparently bound by associative forces rather than by primary valency bonds.

SOCIETY FOR GENERAL MICROBIOLOGY

THE inaugural meeting of the original members of the Society for General Microbiology took place on Friday, February 16, at the London School of Hygiene and Tropical Medicine, through the courtesy of the School authorities. Some two hundred members and friends of the new Society were present.

It may be recalled that the Society owed its formation to the preliminary work done by its organizing committee of some thirty members representative of the various disciplines of microbiology, which held its first meeting in London in the autumn of 1943 under the chairmanship of the late Sir John Ledingham. This Committee realized that the lack of contact between the various specializations in microbiology tended to impede the development of the science as a whole, and as the result of several informal meetings it came to the unanimous decision that the time was ripe to promote the advancement of microbiology by the formation of a society which would provide common meeting ground for those working in the various specialized fields. It was decided that the Society should concern itself with the study of bacteria, viruses, micro-fungi, protozoa and microscopic algae in their various biological activities, it being envisaged, however, that contributions to meetings would deal predominantly with the more fundamental aspects of the study of these forms, including their physiology, nutrition, chemotherapy, systematics and ecology. Subsequent meetings were held which were presided over in turn by Dr Marjory Stephenson and Prof A A Miles, and invitations to become original members of the proposed society were sent out by the secretaries, Dr L A Allen and Dr R St John-Brooks, on behalf of the Committee to a number of microbiologists representative of the various fields. This appeal met with a most encouraging response, and as some two hundred and fifty favourable replies were received, the Committee felt that they had ample grounds for proceeding with the inauguration of the proposed society.

Before the opening of the proceedings at the inaugural meeting, the secretaries read a letter which had been received from the president of the Royal Society, Sir Henry Dale, wishing the young Society every success.

Prof Miles, as chairman of the Organizing Committee, briefly recalled the steps that had led to the movement to inaugurate the Society and asked the members if it was their wish that the Society should be inaugurated on the lines indicated in the proposed rules which had been circulated. The members present, having signified their unanimous assent by a show of hands, the chairman formally declared the Society for General Microbiology to be inaugurated. The office bearers who had been proposed by the Organizing Committee for the consideration of the members of the Society were then unanimously elected. They were as follows: *President*, Sir Alexander Fleming, *Secretaries*, Dr L A Allen, Watford, Herts, and Dr R T St John-Brooks, Lister Institute, Elstree, Herts, *Treasurer*, Mr H J Bunker, *Committee*, Dr C H Andrewes, Prof B T P Barker, Prof A W Downie, Dr H B Hutchinson, Dr B C J G Knight, Dr A T R

Mattick, Prof A A Miles, Dr Muriel Robertson, Dr Kenneth M Smith, Dr A W Stableforth and Dr Marjory Stephenson. The late Sir John Ledingham had also been nominated as a proposed member of the Committee, his untimely death creating a vacancy. Prof Miles then asked the newly elected president to take the chair.

In the course of his presidential address, Sir Alexander Fleming said that the meeting had given birth to a new body corporate, which started with a membership approaching three hundred persons, including many of the leaders in the different branches of microbiology. The meetings which the new Society would hold would bring together workers in the various branches of microbiology who might not otherwise meet and who would thus get acquainted and talking together—it was in this way that real advances were made. Thus bacteriologists, perhaps medical, perhaps agricultural, perhaps industrial, mycologists, academic or industrial, protozoologists with various tastes, or biochemists with interests in all fields were now banded together in this new Society of Microbiology. They had grown up separately, and they had been so busy growing up that they never had time to meet and discuss their common problems until now. He stressed the fact that the new Society did not mean to compete with the existing societies, but had its special aim in the correlation of fundamental knowledge regarding the minute animals and plants which formed the basis of all our studies, rather than the application of the science to the many practical problems which were better dealt with by the older societies. There was ample room for all, and the fact that there had been such a general response to the invitation showed that the Society was going to fill a definite gap. The new Society had been born into a troublous world, and the shortage of paper—an essential metabolite!—would prevent it immediately embarking on the venture of a new journal. He thanked the members present for allowing him to preside over the Society's early infancy and he hoped to be spared to watch his successors lead the Society for General Microbiology along the straight path to honour.

The subsequent proceedings consisted of short addresses by selected speakers on various aspects of microbiology. Dr F M L Sheffield (Rothamsted Experimental Station, Harpenden) read a paper which had been prepared by her colleague, Mr F C Bawden, who was absent from the country, on the importance of the study of viruses to microbiology. Prof W B Brierley (Department of Agricultural Botany, University of Reading) spoke on problems of the micro-fungi, illustrated by reference to *Botrytis cinerea*. Dr C A Hoare (Wellcome Research Institution) chose as his subject biological races in protozoa. Prof R H Hopkins discussed the biology of yeasts. Dr A T R Mattick (National Institute for Research in Dairying, Reading) spoke on fundamental problems in dairy bacteriology. Dr Marjory Stevenson (School of Biochemistry, University of Cambridge) took as her theme "Levels of Microbiological Investigation" and Dr W R Wooldridge (London School of Hygiene and Tropical Medicine) read a paper dealing with the contribution of veterinary science to microbiological knowledge.

In concluding the business of the meeting, provisional rules were adopted and an annual subscription of one guinea was authorized—this amount to be adjusted later on when the journal of the Society came into being.

ABSORPTION, EXCRETION AND LOCAL APPLICATION OF PENICILLIN

THE well-known rapid absorption of penicillin when it is given subcutaneously or intramuscularly and its rapid disappearance from the blood and excretion by the kidneys was mentioned in an earlier article (*Nature*, 677, Nov 25, 1944) J H Humphrey (*Nature*, 765, Dec 16, 1944) concluded from a study of two cases of abortion with extreme oliguria that, when there is no significant renal excretion of penicillin, it is slowly inactivated in the body Sir Alexander Fleming (*Lancet*, 620, Nov 11, 1944) describes, with illustrations, the micro-methods which he has devised for the estimation of penicillin in the blood serum and other body fluids In the same issue of the *Lancet* (p 621) Sir Alexander Fleming, M Y Young, J Suchet and A J E Rowe record their work on the penicillin content of the blood serum after various doses have been given subcutaneously, intravenously and intramuscularly, either as single injections or by continuous drip

The results confirm the fact that penicillin is rapidly absorbed after intravenous or intramuscular injection, disappears rapidly from the blood and is rapidly excreted in the urine After three-hourly doses of 15,000 units, the amount of penicillin in the urine is such that it can be diluted 1,000 times or more and still inhibits the standard test *Staphylococcus* The urine of one patient who had had four injections of 15,000 units at intervals of ten minutes contained at one time just after the last injection so much penicillin that it could be diluted 20,000 times before its bacteriostatic power disappeared Penicillin appeared in the blood a few minutes after a subcutaneous or intramuscular injection, so that little is to be gained by intravenous administration On the other hand, little time must be lost, because the rate of disappearance from the blood does not differ markedly after either intravenous or intramuscular administration Measurable penicillin disappears from the blood "somewhat as follows" after it is given intramuscularly 15,000 units in 2-3 hours, 20,000 units in 3 hours, 35,000 units in 4 hours, 50,000 units in 4-5 hours, 100,000 units in 5-6 hours Thus continuous bacteriostatic power can be obtained in the blood much more economically by smaller doses such as 15,000 units than by larger doses such as 100,000 units Six doses of 15,000 units every two hours (90,000 units) will maintain bacteriostatic powers in the blood for 12 hours, while a single dose of 100,000 units will maintain it for only 5-6 hours It may not be possible, however, to give frequent injections, and sometimes a high concentration in the blood may be desirable for only a few hours, for example, during operations through septic tissues The most economical hospital method of administration seems to be by continuous drip, intramuscular drip being in practice the best Much more work is required to decide whether it is better to maintain a constant low level of penicillin in the blood or to have a very high level for a short time after the injection, followed by a period of very low level before the next injection Clinically both systems have worked excellently

Several methods of giving penicillin intramuscularly have been described H L Miles (*Brit Med J*, 118, Jan 27, 1945) describes one such method of giving it over periods as long as four days In the

same issue (p 122), C E Last describes another method for continuous and accurate intra-muscular administration, and F M Berger (p 116) describes a method of preparing penicillin for systemic administration, the product being, he found, effective, non-toxic and painless

In the earlier note in *Nature* referred to above, the experimental attempt to keep penicillin in the body by giving *para*-amino-benzoic acid as well was mentioned This substance apparently delays the passage of penicillin through the renal tubules The *Lancet* (760, Dec 9, 1944) notes another method of economizing it by incorporating it in an oily excipient designed to delay its absorption: Vegetable oils have been tried for this purpose, but have not been satisfactory M J Romansky and G E Rittman (*Science*, 100, 196, 1944) have, however, had some success with mixtures of peanut oil and beeswax, which have been also used for prolonging the action of histamine and heparin Dispersions of penicillin in this mixture retained their potency for 30-62 days either at 37° C, at room temperature or in a refrigerator Injection of 5,000-10,000 penicillin units in 1 c.c. of this oily fluid into rabbits maintained an inhibitory level in the blood for 6-12 hours, as compared with 2 hours for the same dose of penicillin in saline Injection of 41,000-66,000 units in 2-2.4 c.c. of beeswax oil into three human volunteers gave, it is said, "demonstrable blood levels for 6-7 hours and penicillin was present in the urine for 20-32 hours after the injections" There was no local pain or irritation One dose of penicillin in beeswax oil was given to twelve patients with gonorrhoea and eleven were cured Later a single injection cured fifty-three others (*Bull U S Army Med. Dept*, 1944, Oct, p 42, quoted by the *Lancet*)

Because penicillin is thus rapidly excreted and because the supply of it is, in Great Britain at any rate, still limited, the need for economy of it has led to investigation of the value of local, rather than systemic, administration (*Brit Med J*, 699, Nov 25, 1944) H B May (*Brit Med J*, 817, Dec 23, 1944) reports on its use in private practice, concluding that the general practitioner will use penicillin creams more often than other preparations of it and that these should be made readily available, patients could use them themselves H B May and D Stern (*Lancet*, 83, Jan 20, 1945) describe a rapid method for testing the sensitivity of organisms treated with antiseptic creams containing either penicillin, propylamine, sulphanilamide, gentian violet, proflavine and other dyes Another method of local application is by means of the penicillin pastilles for infections of the mouth and throat described by A B MacGregor and D A Long (*Brit Med J*, 686, Nov 25, 1944, and *Nature*, 201, Feb 17, 1945) These authors had unsuccessfully tried sprays for acute tonsillitis They found that a slowly dissolving pastille with a gelatin base, prepared without excessive heat replaced by another when the first had dissolved, kept the saliva fully bacteriostatic The standard dose adopted was 500 units in each pastille The flora of the condition being treated, as well as the general flora of the mouth, were markedly affected Prof L P Garrod (*Brit Med J*, 528, 1, 1944) has noted that most of the bacteria found in the mouth are sensitive to penicillin The penicillin pastilles seem to have controlled the oral sepsis in the relatively few cases treated by MacGregor and Long The symptoms of Vincent's gingivitis (twenty-five cases), the treatment of which by other methods

had been unsatisfactory, cleared up the most rapidly of all. Both *Treponema vincenti*, the cause of this disease, and the symptoms, disappeared in 24 hours, and within five days the ulcerated areas had cleared up so well that the treatment was stopped. No recurrence had been noticed up to 3½ months later. Acute hæmolytic streptococcal tonsillitis (seventeen cases, including four cases of scarlet fever) seemed to respond clinically to the pastilles and the effect on the throat flora seemed to be rapid. Carriers of these streptococci (twelve cases) became negative during treatment, but when the pastilles were stopped, the infection reappeared. This method of using penicillin is clearly promising and, as these authors say, more work on it is required. It certainly seems more promising than the use of sulphonamides in the form of lozenges, for Capt. A. F. Hayden and Lieut.-Colonel J. W. Bigger (*Brit. Med. J.*, 81, Jan. 20, 1945) conclude that these are not satisfactory for the prevention of respiratory tract infections, including coughs and colds.

Yet another means of local application of penicillin are the penicillin lamellæ for eye affections described by Wing-Commander J. C. Neely and Squad Leader A. G. Cross (*Lancet*, 85, Jan. 20, 1945). These authors noted that solutions of calcium and sodium penicillin deteriorate, even at 0°C, and tend to become infected with organisms insensitive to penicillin. They devised lamellæ made with lactose, the use of which in a small number of cases suggests that they are as satisfactory as penicillin drops. They retained their potency for two months at room temperature. Gelatin lamellæ rapidly lost their potency. In an Annotation in the same issue, the *Lancet* (p. 92) remarks that expectations of the value of penicillin for eye infections may not be realized, but that it is the drug of choice for gonococcal ophthalmia neonatorum, and that it is valuable for chronic ulcerative blepharitis, acute gonococcal iritis and for severe infections and war wounds of the eye (given as an irrigation of the anterior chamber). On the other hand, Sir Arnold Sorsby and E. Hoffa (*Brit. Med. J.*, 114, Jan. 27, 1945) conclude, after treating forty-seven infants suffering from ophthalmia neonatorum due to the gonococcus and other organisms with penicillin drops in various concentrations, that penicillin, if it is in adequate concentration, appears to be effective against all the organisms which commonly cause ophthalmia neonatorum, and that the results obtained with it are of the same order as those obtained with the sulphonamides.

Penicillin, indeed, seems to have many advantages over the sulphonamides, its lack of toxicity being one of the greatest. The *Lancet* (55, Jan. 13, 1945) reviews research on the penicillin treatment of gas gangrene (see also *Nature*, 677, Nov. 25, 1944) and quotes work which indicates that penicillin is superior to the sulphonamides for the treatment of this condition. Its precise value requires, however, further elucidation. G. H. Tee (*Brit. Med. J.*, 118, Jan. 27, 1945) reports on the treatment of one case of meningococcal meningitis with penicillin, suggesting that, although penicillin given intramuscularly may not normally get into the cerebro-spinal fluid, it may do so under the abnormal conditions of meningitis. R. E. Rewell, in the same issue (p. 119), describes the treatment of one case of internal hydrocephalus, arising as a complication of pneumococcal meningitis, with penicillin and sulphathiazole. All cases of pneumococcal meningitis should, this author thinks, be given penicillin as soon as possible. G. LAPAGE

BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

THE twenty-fourth annual report of the British Electrical and Allied Industries Research Association (E.R.A./T. 352) summarizes the work which has been carried out during the year ended September 30, 1944, and again lists, by titles, the various research reports which have been issued during the year. The work is reviewed under the same eighteen major classifications as last year, among which dielectrics, electric control apparatus, and surgical phenomena are prominent. The work of the Association has been carried on during the year by 111 active technical sections, committees, sub-committees and panels, and seventy technical reports on various subjects have been issued as compared with seventy-five in the previous year.

Two outstanding matters mark the conclusion of the Association's year. The first is the retirement of the director, Mr. E. B. Wedmore, and the second is the project for the establishment of new laboratory accommodation at Leatherhead. In view of the necessary expansion of research programmes and the need for achieving results in advance of the practical developments to which they apply, it is becoming increasingly evident that the limiting factor will be the shortage of adequately trained personnel, a condition which can only be relieved adequately by even more extensive pooling of problems of common interest. The Association has now secured control of some forty-seven acres of land at Leatherhead at a cost of about £25,000. Designs for the new laboratories, plant and office accommodation are in the hands of Mr. H. J. Rowse, who has already spent considerable time studying the nature of the activities of the Association's staff, so that the building arrangements may foster and facilitate their work. Plans will be ready for consideration at an early date.

Further diminution of enemy action in the London area and smoother working of industrial organization to take care of war requirements has made possible some increased activity of committees, both those indirectly connected with war products and those concerned with essential contributions of the E.R.A. to all sections of the industry.

The latest agreement with the Department of Scientific and Industrial Research was due to terminate at the end of the year covered by the present report, but the agreements have been extended for a maximum period of two years. In doing so the Department restored the sliding-scale grant to the £1 for £1 basis. It has become apparent that many influential persons in the electrical industry who are not closely in touch with the details of technical and scientific developments are not fully informed of the nature and importance of the use that is made of the Association by the industry. To remedy this, and for the information generally of interested parties, a descriptive illustrated brochure entitled "Co-operative Electrical Research" (E.R.A./R619) has now been prepared and issued. This brochure deals with the past, present and future of electrical research, the activities of the E.R.A. and its association with other bodies in the industry, and an outline of some of the major researches carried out by the Association.

A detailed account of the technical and scientific activities of the Association during the year is given in the body of the report under numerous sectional headings.

igs The co-ordination of all research work connected with the applications of electricity to agricultural and horticultural work is now almost complete plans have been prepared during the year for the establishment of a field station associated with the University of Reading, and a working liaison has been established with the Scottish Hydro-Electric Board.

Special attention has been given to research required for the further commercial development of gas-blast circuit breakers The electric control apparatus section has prepared a further important series of reports for dealing with industrial explosion hazards The importance of work on the creep of steels has been recognized by expansion of the scale of working at the National Physical Laboratory, and some success has been achieved in applying similar ideas in the study of insulating materials subjected to continued high mechanical stresses at working temperatures, a subject representing practically an unworked field until tackled by the Association

Continuous attention has been given to the examination of new insulating materials and to the research necessary for their standardization, and generally to improvements in methods of selection and testing The practical value of applying modern statistical and other scientific methods in the study of electricity supply technology is receiving increasing recognition, and when the War ends will, no doubt, be pursued on a more adequate scale. Several notable reports have been issued during the year applying to surge phenomena, transformer design and meter jewels Work on interference with communication circuits which applied mainly to particular war products has led indirectly to an important new development affording a scientific basis for the design of ignition systems adapted to all types of engines and to varied working conditions

CERAMIC SEQUENCES AT TRES ZAPOTES, MEXICO

THE second season's work of the National Geographic-Smithsonian Institution joint archaeological expedition to southern Veracruz in 1940 has now been described in Bull 140 of the Bureau of American Ethnology* Bull 139, giving an account of the 1939 season's work by G. W. Weiant, has already been noticed in *Nature* (July 22, 1944, p. 124) The aim of the 1940 work, by Philip Drucker, was to follow up the preliminary exploration of 1939 with careful stratigraphical excavations, upon which a ceramic sequence could be based The results indicate no considerable alterations in Weiant's succession of evidence is not absolutely conclusive on every point, but it is sufficient to confirm the suggestion made in the previous notice that his publication was premature

The chief result of the 1940 work was to mark the essential unity and continuity of the Lower, Middle and Upper Tres Zapotes 'periods', which are renamed 'phases' to emphasize the point, and to separate Weiant's Upper period into a true Upper Tres Zapotes phase and an unconformable "Soncautla Complex", consisting of cremated burials (the "cremated burials covered bowls" of the previous notice) intruded into deposits of the Upper phase. The Tres Zapotes

period, *sensu stricto*, is shown to cover an occupation of long duration, after which the site was abandoned, and later used for the Soncautla burials for a short time. So far, the picture is entirely convincing, but Drucker also points out that he cannot confirm Weiant's division of the Middle period into A and B stages, admitting at the same time that this may be due to the absence of A deposits from the places excavated by him

Much of the material found in the 1940 work consists of sherds, and this has imposed a simpler system of classification than Weiant's, in which a relatively small number of wares are based on characteristics of slip, vessel shape and paste The distinguishing features of the Lower, Middle and Upper Tres Zapotes phases are clearly pointed out in terms of these wares The figurines are divided into three main types, the first to appear, which persisted throughout, are hand-made and mostly solid, whereas the other two are found in the Upper phase only, one being hollow moulded and the other large and elaborately modelled by hand, with jointed limbs

A tentative chronology of the site is sketched out, and in this connexion there are two strong indications of an early date in the complete lack of metal and of Plumbate and Fine Orange wares The Lower Tres Zapotes phase is shown to be linked with the early Lowland Maya, to the exclusion of the early Highland cultures such as those of Monte Alban and the Valley of Mexico It is suggested that it was in existence in the first century B.C. The Middle phase is essentially one of transition, but the Upper is marked by a large increase of Polychrome sherds, and the introduction of some new elements which, it is conjectured, may have diffused from Teotihuacan The date of the close of the Tres Zapotes occupation is estimated in round figures as A.D. 1000 This was followed by a period long enough for the accumulation of a certain amount of humus, after which came the Soncautla burials, which are very tentatively ascribed to the thirteenth century

This bulletin shows a very considerable improvement on No 139 in the provision of scales on illustrations and plans. Three misprints in references to plates were noticed plate 18 at the top of p. 41 should be 16, Plate 10 at the bottom of p. 43 should be 14, and plate 56 on line 9 of p. 84 should be 59.

G. H. S. BUSHNELL

FORTHCOMING EVENTS

Saturday, March 17

BIOCHEMICAL SOCIETY (at the Middlesex Hospital Medical School, London, W.1), at 2 p.m.—Annual General Meeting

INSTITUTION OF MECHANICAL ENGINEERS (GRADUATES' SECTION) (at Storey's Gate, St. James's Park, London, S.W.1), at 3.30 p.m.—Mr. A. H. Lloyd "British Machine Tools during the War" (Annual Lecture)

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Prince's Gate, South Kensington, London, S.W.7)—Mr. L. V. Chilton "First Renwick Memorial Lecture"

Tuesday, March 20

ROYAL SOCIETY OF ARTS (DOMINIONS AND COLONIES SECTION) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. A. C. Thaysen "Food Yeast, its Nutritive Value and its Production from Empire Sources"

CHEMICAL ENGINEERING GROUP (SOCIETY OF CHEMICAL INDUSTRY) (joint meeting with the INSTITUTION OF CHEMICAL ENGINEERS) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Industrial Research" (to be opened by Dr. E. W. Smith)

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Henry Dale, O.M., Pres. R.S. "Nerve Endings and Chemical Transmitters", (3) "Cholinergic Action in Nerve Ganglia. Motor Nerve Endings and Electric Organs"

* Smithsonian Institution Bureau of American Ethnology Bull. 140. Ceramic Sequences at Tres Zapotes, Veracruz, Mexico. By Philip Drucker. Pp. ix+155+65 plates (Washington, D.C. Government Printing Office, 1944) 50 cents

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p.m.—Discussion on "Apprenticeship and Trainee Systems in the Radio Industry" (to be opened by Dr J Greig)

INSTITUTE OF THE PLASTICS INDUSTRY (at the Waldorf Hotel, Aldwych, London, W C 2), at 6 p.m.—Mr N J L Megson "Plastics at War"

PHARMACEUTICAL SOCIETY (at 17 Bloomsbury Square, London, W C 1), at 7 p.m.—Mr W K Fitch "Pharmacists with the B L A"

Wednesday, March 21

INSTITUTION OF NAVAL ARCHITECTS (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 12 noon—Eighty-sixth Annual Meeting

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the INSTITUTE OF PHYSICS) (at the Royal Institution, Albemarle Street, Piccadilly, London, W 1), at 2 30 p.m.—Prof H T S Britton "The Mechanism of Electrode Measurements"

PHYSICAL SOCIETY (COLOUR GROUP) (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S W 7), at 3 p.m.—Dr R K Schofield "The Presentation of the C I E System of Colour Specification"

ILLUMINATING ENGINEERING SOCIETY (joint meeting with the ROYAL METEOROLOGICAL SOCIETY) (in the large Physics Lecture Theatre at the Imperial College of Science, Imperial Institute Road, South Kensington, London, S W 7), at 5 30 p.m.—Mr J M Waldram "Measurement of the Photometric Properties of the Upper Atmosphere"

Thursday, March 22

LINNEAN SOCIETY OF LONDON (joint meeting with the ZOOLOGICAL SOCIETY OF LONDON) (at Burlington House, Piccadilly, London, W 1), at 4 p.m.—Mr I H Burkill "Abnormal Gamopetalous Flowers of the Poppy, *Romneya Coulteri*, and the way in which its Sepals Protect the Sexual Organs", Prof D M S Watson, F R S "Evolution of the Elephants"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 15 p.m.—Sir Lawrence Bragg, F R S "Some Physical Problems of the Solid State"

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 6 30 p.m.—Mr R H Bound "Hydraulics for Aircraft"

Friday, March 23

ASSOCIATION OF APPLIED BIOLOGISTS (joint meeting with the GENETICAL SOCIETY) (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 11 a.m. and 2 15 p.m.—Symposium on "Genetical Relations of Plants and Animals to their Pests and Diseases" (Speakers: Dr C D Darlington, F R S, Dr J Hammond, F R S, Mr M S Pease, Mr J G Carr, Mr W Black, Mr G Cockerham, Mr T J Jenkin and Dr C B Williams)

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Sir Richard Paget, Bart "Is Human Speech Good Enough?"

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the INSTITUTION OF ELECTRICAL ENGINEERS) (at Storey's Gate, St James's Park, London, S W 1), at 5 30 p.m.—Mr W B Shannon, Mr C W Pratt, Mr T B Webb and Mr W B Carlson "Expanded Tube Joints in Boiler Drums—with Special Reference to the Battersea High-Pressure Boilers"

Saturday, March 24

ASSOCIATION OF BRITISH ZOOLOGISTS (at the Zoological Society of London, Regent's Park, London, W 1), at 10 a.m.—Tenth Annual General Meeting, at 10 30 a.m.—Dr C F A Pantin, F R S "The Interrelationship of Biology Teaching in Schools and Universities", at 2 p.m.—Dr Stanley Kemp, F R S "Marine Investigations", at 2 45 p.m.—Dr S A Neave "The Work of the Zoological Society", at 3 30 p.m.—Mr J C F Fryer "Zoological Interests of the Agricultural Research Council", at 4 15 p.m.—Dr E B Worthington "Freshwater Investigations"

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 2 30 p.m.—Mr J H Ridley "An Experimental Approach to Time Lapse Cinematography"

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the SOUTH YORKSHIRE SECTION OF THE ROYAL INSTITUTE OF CHEMISTRY) (at 198 West Street, Sheffield, 1), at 2 30 p.m.—Dr U R Evans "The Principles governing Corrosion Resistance in Metals and Alloys"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ENGINEER AND MANAGER—The Clerk to the Alderley Edge and Wilmslow Electricity Board, 49 Spring Gardens, Manchester 2 (March 21)

ANIMAL HUSBANDRY OFFICER—The Executive Officer, Cornwall War Agricultural Executive Committee, County Hall, Truro (March 21)

ASSISTANT VETERINARY INVESTIGATION OFFICER at the University Agricultural Advisory Centre—The Secretary and Registrar, The University, Bristol (March 24)

PRODUCTION OFFICERS IN THE DEPARTMENT OF AGRICULTURE, Government of Nigeria, for Agricultural Surveys connected with investigations of Diseases of Cocoa—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3752 A) (March 24)

GRADUATE ASSISTANT to teach MATHEMATICS and SCIENCE—The Principal, Twickenham Technical College, Egerton Road, Twickenham, Middlesex (March 26)

LECTURER IN BIOLOGY in the Cardiff Technical College—The Director of Education, City Hall, Cardiff (March 28)

RESEARCH OFFICER on the staff of the Council for Scientific and Industrial Research (Division of Industrial Chemistry), Melbourne for research work in CERAMICS—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W C (April 2)

LECTURER (full-time) IN CHEMISTRY in the Department of Chemistry Leeds College of Technology—The Director of Education, Education Offices, Leeds 1 (April 7)

MATHEMATICS SPECIALIST (permanent) to teach up to Higher School Certificate and University Scholarship standard, and an ASSISTANT (temporary) to teach BIOLOGY and CHEMISTRY to Junior Forms, at the Vardean School for Boys—The Education Officer, 54 Old Steine Brighton (April 7)

PHYSICIST (full-time) at the Radiotherapeutic Centre—The Secretary Superintendent, Addenbrooke's Hospital, Cambridge (April 7)

LECTURER (full-time) IN PHYSICS—The Principal, College of Technology and Commerce, The Newark, Leicester (April 9)

ASSISTANT LECTURER AND DEMONSTRATOR (woman) IN BOTANY—The Principal, Royal Holloway College, Englefield Green, Surrey (April 21)

SECRETARY TO THE SENATE—The Principal, University of London c/o Richmond College, Richmond, Surrey (April 30)

TUTOR IN PHYSIOLOGY—The Principal, Lady Margaret Hall Oxford (April 30)

LECTURER, and an ASSISTANT LECTURER AND DEMONSTRATOR in the DEPARTMENT OF PHYSICS—The Registrar, University College Cathays Park, Cardiff (April 30)

PRINCIPAL—The Secretary, King's College of Household and Social Science, c/o University College, Leicester (May 1)

UNIVERSITY CHAIR OF BACTERIOLOGY tenable at University College Hospital Medical School—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (June 25)

TEACHER (full-time) OF PHYSICS AND MATHEMATICS—The Clerk Northern Polytechnic, Holloway Road, London, N 7

SPEECH THERAPIST—The Education Officer, County Hall, Wakefield, Yorks

PSYCHOLOGIST (part-time) to the Child Guidance Clinics at Huyton and Atherton and Ashton-under-Lyne—The County Medical Officer of Health, School Medical Department, County Offices, Preston

ROUGH ENGINEER AND SURVEYOR—The Town Clerk, Town Hall Wallasey

RATIONALIZATION OF LOCAL GOVERNMENT IN BRITAIN

THE White Paper on Local Government in England and Wales during the Period of Reconstruction* may be pragmatic, but no one could claim that it is bold or imaginative. The assumption that opposition to any drastic innovation such as regional government makes such a step inexpedient during the reconstruction period may be well founded. Furthermore, it is probably true that some improvement in administration might be achieved without abandoning the main features of the county and county borough system, subject to the establishment of appropriate machinery where it is shown to be necessary for combined action by neighbouring areas. But the central, and indeed only, recommendation of the White Paper is the establishment of a Local Government Boundaries Commission. The field of joint authorities is regarded as the most suitable for the development of units of administration where large areas are required, and within its limited field the proposed commission may have considerable advantages. Centralizing in one body, subject to review, all boundary questions, would promote the accumulation of an unrivalled fund of experience and enable the relations of county and county borough, of town and country, to be seen clearly and regulated as a whole. It would also be an advantage to have much of the work done on the spot with a full use of local knowledge, and if the commissioners are skilful in promoting local agreement, it should lead to substantial economies in the cost of boundary alterations.

Part 2 of the White Paper, forming the major section, is devoted to this procedure for adjustment of local government areas. It is frankly recognized that the system of counties and county boroughs cannot be static, but must be capable of adaptation by changing boundaries to meet changing conditions. The proposal to improve the effective machinery for periodic review has been hailed as a solid and promising advance, and the proposed boundary commission appears to meet the conditions put forward in the White Paper, namely, it must command public confidence, it must work smoothly and expeditiously, it should be such as to reduce to the minimum the cost of making the adjustments, and it must ensure that all the proposals affecting a county, whether for adjusting county districts or altering the boundaries between county and county, or county and county borough, are properly correlated and not considered in isolation.

It is not for this positive proposal that the White Paper is to be regarded as weak and disappointingly cautious. It is because the proposal, however sound in itself, only touches the fringe of the problem, and because the analysis of the problem is hesitant and shallow. Nowhere are the fundamental issues laid bare. There is no contribution to that fundamental thinking about the relations of local and central government which is indispensable if we are to evolve

* Cmd 6579 (London H.M. Stationery Office, 1945) 4d net.

machinery adequate to serve the needs of to-day, either at the centre or at the circumference. Finally, as a contribution to the education of public opinion on the issues involved, the White Paper compares unfavourably with those that have been issued on other questions such as employment policy, education, health—with all of which this issue of local government reform is closely concerned. The White Paper, for example, indicates the two main arguments for large units: that many local government authorities are too small to provide the new and extended services required in these and in other fields, and the inadequacy of the present system of local authority finance, based upon property rates, to maintain existing burdens or ensure their independence. But it fails conspicuously to point out that if regional development is inexpedient at the moment, it is on account of local prejudices which have no sound or rational basis, but which it should be the work of time and education to remove. Nor is there any reference to that scientific study of the rating system and its variations in incidence, sponsored by the National Institute of Economic and Social Research, in which Prof. J. R. and Mrs. Hicks have shown the tangle, also disclosed by the Fitzgerald Committee, which must be unravelled before the system can be brought back to life and the independent income of the local authorities substantially increased.

The White Paper, indeed, compares poorly with reports like that of the committee of the National Association of Local Government Officers on the reform of the local government structure, or of the Labour Party on the future of local government, or with Dr. D. M. Goodfellow's "Democracy and Local Government" issued by the Association for Education in Citizenship as No. 12 in the Handbooks for Discussion Groups series. While Dr. Goodfellow only deals incidentally with some of the reasons that are forcing the reconsideration of the relations between local and central government, he indicates clearly enough the weaknesses of the existing system and the questions that should be asked. His pamphlet is admirably designed to stimulate that closer discussion and wider public interest which are indispensable conditions of effective local government reform and of the continued functioning of our democratic institutions. He is concerned with the general question; and while he brings certain aspects of it into clear focus, for example, that of the entry to, and staffing of, the local government service and the reasons for regional proposals, he does not enforce consideration of the problem as an urgent practical issue in the same way that recent Government proposals have done in such fields as those of town and country planning, health and education. Moreover, it is scarcely so suggestive in regard to constructive proposals as Guy. Hunter's admirable pamphlet, "The British Way in Local Rule", in the British Way series. Writing before the publication of the Beveridge Report, Mr. Hunter contributes a critical review of our present social services under

local government and also anticipates strikingly some of the proposals and implications in this field of the Beveridge Report, and the White Papers on Educational Reconstruction and a National Health Service, for example.

In its scheme for educational reconstruction in Britain, the Government could not avoid some revision of the present system of local educational administration to meet the needs of a new statutory system of public education. Whether or not the proposals of the White Paper on local government are those best calculated to preserve and stimulate local interest in educational matters and at the same time secure both efficiency and a really national system, the proposal that the councils of the counties and the county boroughs only shall be the local education authorities, with powers to combine for educational purposes, is advanced from departmental considerations alone. It has no relation to the grouping that might be most profitable from a general or national point of view, and it is already evident that the proposed system offers no safeguard that the outlook and resources of the local education authorities will ensure uniformity in such a matter as the salaries and status of the teachers.

The existence of such dangers is shown very significantly in independent surveys such as McCollvin's report on the public library services, and it is particularly apparent in proposals for a national health service. The Government's White Paper on health starts with the view that there is no case for departing generally from the principle of local responsibility, coupled with enough central direction to obtain a coherent and consistent national service, but it recognizes the need within the administrative structure for some largely professional body which can concern itself with the professional welfare of medical practitioners who take part in the service. None the less, for the future hospital service, it will be essential to obtain larger areas than at present, both for planning and administration. Most of the areas of the existing authorities fail to meet the essential needs of an organized area, namely a population and financial resources sufficient for an adequate service to be secured on an efficient and economical basis; a type where town and county requirements can be regarded as blended parts of a single problem and catered for accordingly, and definition as to allow of most of the varied hospital and specialist services being organized within its boundaries, leaving for inter-area arrangement only a few specialized services. Outside the hospital and consultant service, the Government holds that existing organizations should be upset as little as possible consistent with achieving a unified health service for all. While still conducted locally with all the advantages of local knowledge and enthusiasm, they should be regarded in future as the related parts of a wider whole, and should fit in with all the other branches of a comprehensive service in their planning and distribution. To secure this, the Government proposes a new joint authority, again presumably responsible for planning from a purely departmental point of view.

The argument for some comprehensive regional plan is set forth even more cogently by Sir Arthur MacNalty in the Nu field College paper "The Reform of the Public Health Services". Sir Arthur indicates the imperative need for a large administrative area in respect of the maternity and child welfare services, the school medical service, infectious diseases, tuberculosis, venereal diseases, cancer, rheumatic diseases, as well as hospital services and general practitioner services. He proposes to provide the co-ordinated effort between local authorities by a system of regional health councils, and there is much to be said for such an arrangement, coupled with a Government undertaking to tackle the whole problem of adapting local government machinery to modern needs as soon as circumstances permit.

In health, as in other fields, an adequate programme of reform and reconstruction cannot be executed without creating the appropriate planning machinery at the centre, and forming units large and competent enough to administer and execute the policy over areas large enough for efficiency. The debate on the Town and Country Planning Act in the House of Commons showed how urgent in that field is the need for some adjustment of local government boundaries and resources, or some further measure of Government support.

It must also be recognized that we cannot continue to frame policies for re-building, for town- and country-planning and for the re-organization of education, health and other services, without giving thought to the repercussions of such policies on the structure of local government as a whole. Constructive thought about the principles and whole relation of local administration to the central government is required. It is not sufficient to recognize that certain public services require for their efficient operation administrative areas substantially larger than those of many of the existing local authorities. We must distinguish clearly the contribution which local support and interest can make to the effectiveness of those services, and we must see that departmental proposals are duly co-ordinated and harmonized with one another and with the needs of the situation as a whole. This the report of the Liberal Party Committee on Local Government conspicuously fails to do. The report is disturbing as well as disappointing, not merely for the absence of any constructive proposals, but still more for the refusal to recognize the necessity of some form of regionalism.

Much of the material proper to an inquiry into local government reform and basic to a decision on policy has already been collected and is available in such reports as those of the Barlow Commission and the Uthwatt and Scott Committees. The facts are largely displayed already. The need now is rather for clear and constructive thinking about the facts, analysis of the evidence, the formulation of principles and policy, and the courage to take the necessary decisions to execute a reasoned policy, whether or not that appears to conflict with what may be regarded as the traditional or vested interests of a particular professional body or local council.

In the attempt to view as a whole the effect upon the general structure of local government of the changes in administrative areas which are inherent in the extension of the scope of particular social services, there must first be faced the main question. Should the present tendencies to mark out large administrative areas for each main service, mainly on purely technical considerations, be permitted to proceed unchecked, or should an attempt be made to find a single comprehensive area of large size which would serve tolerably well for the administration of all or most of the extended services? But a decision on this point of area is bound up with questions of the constitution and powers of the new regional authorities. For those there appear to be three possible types: an *ad hoc* authority, a joint authority or a compendious primary authority of the type of the existing local authority. Here again, as in the choice between an elective or nominated body, exercising either executive or advisory powers, the decision must be determined by the view we take of the relation between local and central government, and of the way in which that relation can best give expression to the democratic ideal.

The decisions to be taken do indeed depend on first principles, and whatever intermediate forms of government are evolved must conform to those principles laid bare in the Machinery of Government Report nearly three decades ago. That is what presumably is being considered *inter alia* by the Committee of Ministers and the interdepartmental committee of permanent heads of departments, which already in 1943 were understood to be at work on the machinery of government. It is with that in mind that the present White Paper on local government appears to be so disappointing; so far from laying bare the fundamental issues, it is at pains to cover them up and to temporize.

Given the assurance that the fundamental issues were really being faced and that a serious attempt was being made by the Committee of Ministers and the interdepartmental committee to arrive at a comprehensive solution and not to postpone decision or action, the proposals of the White Paper might be accepted without prejudice so far as they go. Some real effort must, however, be made to deal constructively and nationally rather than departmentally with the outstanding questions, pending the reports of these committees. It must be remembered that it is no bad thing in itself that we should retain the wider freedom of experiment at this juncture that is possible, for example, with local administration, or even with regional administration, in such fields as education and health, as compared with a fully centralized national system, where the consequences of a mistake may be so much more serious. Again, the effectiveness of local government clearly depends on the extent to which it can attract the right type of men and women and secure the wider interest and support of the community. It is part and parcel of that process of re-integration in which civil defence has already shown the way in promising experiments and on which the report of the Commission of the

Church Assembly in "The Church and the Planning of Britain" rightly laid such stress. There above all lies the real solution of the problem of town- and country-planning and the location of industry, of central and local government. Handled wisely, the new extension of the social services, as Sir William Beveridge has been quick to note, gives us opportunities of harnessing to the evolution of a constructive democracy new interests and new forces in an increasing proportion of the population. If that is to be achieved, however, there must be proceeding at the centre, the careful thought, inquiry and analysis necessary to lay down the pattern of organization within which those new interests and forces can function and find effective expression.

Regional government is now inevitable, but it is essential that it should not be a form of provincial bureaucracy, and that it should be viewed and established in the right relation to the local councils and authorities and to the central government, and that there should prevail the spirit of co-operation and goodwill without which no organization can function effectively. It should be remembered that it is the multiplicity of independent local authorities that is the problem. The local council provides and must continue to provide, as Mr Guy Hunter points out, the local leadership, the inspiration to the citizen to make the plan for Britain a plan for his town and street, to give his service voluntarily and with zest; to see a tangible result of local rule and take his part in it. Only at this level can we hope effectively to harness to our post-war purposes, the enthusiasm and unselfishness which have found expression in civil defence; and on the local authority, too, must lie a large measure of responsibility for the execution of our plans for better education, health and other social services. Again, not only will there come locally, within the limits of the regional plan, the internal planning of the town or district, but also the capacity for experiment and variation which is so much harder for the central government to attempt.

At the regional level will come those plans which must cover a wider area, as emphasized in the debates on the Town and Country Planning Act, particularly with reference to the replanning of destroyed cities and the problem of 'overspill', or of population as in Sir Arthur McNulty's proposals for the health service. Here we should seek to achieve the proper balance between town and county, industry and agriculture, between central and local control. Finally, at the national level, under the eye of Parliament, the broad national plan and lines of policy must be determined, the balance held between regions, and the solution of legal and financial obstacles to planning found. Here alone can we look for the slow adaptation of the whole system to the changing needs of the national community, and ultimately of the world as a whole. This can never be achieved without the continuous devolution of local responsibility for the execution of policy as far as possible. If regionalism is required to provide the resources for tackling some of our urgent post-war problems, it is equally required to relieve the central government of some of its burdens. But that

can only be done when there is creative thinking about the first principles of the machinery of government, and the clear enunciation of policy and the taking of decisions which will allow regional and local authorities to proceed in their own sphere with confidence. Hitherto there has been little sign of this at the centre, the Requisitioned Land and War Works Bill is the latest of a series of measures in which national planning is conspicuously absent and in which the Government has eschewed any attempt to see that departmental views and prejudices do not override the general interest even to the thwarting of a national plan.

Courage and vision are the first requirements. courage to grapple with whatever private or vested interests obstruct progress, and vision to see the possibilities of a civil or local government service fitted by training and experience to concern itself with the achievement of immediate concrete purposes. The fear of bureaucracy typified in the Liberal Party report will never allow us to achieve the possibilities inherent in a 'positive' Civil Service wholeheartedly with the people and eager in its struggle for a fuller human life. As John MacMurray has pointed out, under positive government there must be a considerable extension of local rule, and the new conception of the Civil Service and of the functions of central government depend on a lively and effective participation in self government by the general body of citizens. But without courage and the readiness to shed prejudice, we shall never achieve the forms of government which make such participation effective, and at the same time secure the continuous application of scientific knowledge and technique to the betterment of the conditions of human life. To be timid, no less than to be weak, is to be miserable.

BIOCHEMISTRY OF PROTEINS

Advances in Protein Chemistry

Edited by M. L. Anson and John T. Edsall. Vol. 1. Pp. xi + 341. (New York: Academic Press, Inc., London: H. K. Lewis and Co., Ltd., 1944.) 5.50 dollars.

FEW would deny that protein chemistry, in all its aspects, is one of the most important branches of biochemistry. Not only do the proteins constitute a unique group of related compounds containing numerous types and perhaps an infinity of individuals, but also their functions are many and diverse, each type appearing to be adapted to one particular function. They form, for example, hormones, antibodies, genes and, either alone or in association with prosthetic groups, enzymes and respiratory pigments. The proteins clearly offer for investigation a wide field and a multitude of problems, the complete solution of which would probably yield the key to the elucidation of the nature of living matter. On these grounds we welcome this, the first of a series of volumes to be devoted exclusively to advances in protein chemistry. Nevertheless, when we reflect that there already exists an extensive review literature on biochemistry and related subjects, and that much of protein chemistry is inseparable from other branches of biochemistry, we foresee some danger of a considerable duplication of subjects in the various

reviews That such a danger exists is, indeed, apparent from the present volume, which contains several articles dealing with topics which have recently been reviewed elsewhere

It was apparently the intention of the editors to publish in each volume articles by various authors dealing with related subjects. In their preface they state that the second volume will be devoted mainly to protein nutrition, and that in the first "special emphasis is laid on proteins as they occur in nature, as components of complex biological systems" The latter statement is, however, scarcely borne out by an examination of the volume It consists, in fact, of eight articles dealing with widely differing subjects

As is to be expected in a volume of this kind, the articles are of varying quality and interest Some give excellent accounts of the subjects with which they deal As examples may be specially mentioned those dealing with immunology and muscle proteins For those who are not conversant with the relationship of immunology to proteins, the former provides an excellent introduction. The subject and its terms are first concisely explained in such a manner as to render intelligible the description of the more recent work which forms the main subject of the article In our opinion this is a model of what a review should be. In the same category, although dealing with a less extensive field, is the article on muscle proteins The main subject of this is, of course, the protein myosin, and the results described illustrate the inseparability of protein chemistry from biochemistry In myosin one encounters a protein which apparently serves a dual function, probably acting as an enzyme (adenosinetriphosphatase) and also forming the contractile element of muscle In so far as they have been analysed, there is a striking similarity in the composition of the myosins from different species, but the author is wise not to draw the conclusion that all myosins, or even some of them, are chemically identical. Similar resemblances in composition occur among other proteins serving identical functions in different species, and, as is pointed out in the article on immunity, the more nearly related the species from which analogous proteins are obtained the greater is the serological relationship, as evidenced by cross-reactions, between them The diminution in the serological relationship as the species diverge is no doubt due to the proteins becoming more dissimilar in composition This suggests that the species specificity of proteins is, in general, a reflexion of the specificity in the protein forming the genic material of the gametes

Another article deals with the structural proteins of cells and tissue and gives a brief résumé of a recent symposium on cytochemistry But it is chiefly concerned with the results obtained by the examination by physical methods of proteins, or of structures which are believed to consist of protein, or to contain a protein component There are, for example, a few interesting electron micrographs of structures such as sperm tails which illustrate the possibilities of the electron microscope But this must at present be regarded as morphology rather than protein chemistry.

The article entitled "The Purification and Properties of Certain Protein Hormones" is sufficiently described by its title if it is mentioned that it is limited mainly to hormones from the pituitary gland, and does not describe their physiological properties. Those who have always regarded adrenaline as a hormone will be surprised to read in the introductory sentence "All the animal hormones which

have been isolated so far are either steroids, proteins, or polypeptides" Surprise may also be felt at the prospect of the possible revival of Abel's so-called unitarian theory of the hormones of the posterior lobe of the pituitary According to the author, however, a protein apparently possessing the characteristics of a pure substance and exhibiting both oxytocic and pressor activities has been isolated from the posterior lobe.

Short articles discuss soy-bean protein in human nutrition (this might well have been held over for the second volume), the combination of calcium with protein, and lipoproteins.

The longest, and hence the main, article of the volume is entitled "Nucleoproteins". This is comprehensive in scope, dealing with nucleic acid, nucleoproteins, protamines and histones, viruses and cytochemistry This group of subjects undoubtedly constitutes a very attractive section of biochemistry, but unfortunately the treatment of it is marred by the author's discursive style, by the inordinate length of the sections dealing with the obscure phenomenon of the 'depolymerization' of nucleic acid and related subjects, by the over-emphasis of some details and the omission of others, and by the adoption of a descriptive method for recording deductions from the results of cytological experiments, a method which tends to elevate hypotheses to established facts Limitations of space preclude a detailed criticism of this review, but a few specific points may be mentioned.

It is emphasized that the deoxyribonucleic acids in the nuclei of different types of cells may not be identical, but no mention is made of Feulgen's isolation in 1937 of nucleic acid from the nuclei of rye embryos and its chemical identification as thymus nucleic acid, which has an important bearing on this point. On p 214 it is stated that the ribonucleic acid from the pancreas yields the same kind and proportion of bases as yeast nucleic acid This ignores Jorpes' work (1934), which seemed to show that the purine bases were in a different ratio In the absence of decisive evidence to the contrary, this may mean that the cytoplasmic 'nucleic' acid of all animal cells is of the pancreas and not the yeast type. The acceptance, on slender evidence, of the view that a ribonucleic acid is present in nuclei obscures the otherwise established fact that the name nucleic acid is correct as applied to deoxyribonucleic acid but a misnomer for ribonucleic acid The classification of globins as histones is incorrect They differ in their mode of occurrence and composition as well as in their chemical and physiological properties The old analytical data for thymus histone, reproduced in Table IV, are clearly unreliable and should be replaced by the more limited data provided by Felix (1931), which leave no doubt about the presence of sulphur On p 266 it is stated that chromosomes appear "to join and disjoin during separate phases of the mitotic cycle" Kossel's hypothesis of the direct conversion of complex proteins into histones and of histones into protamines, to which so much prominence is given, is improbable and has no experimental basis Finally, the apparent acceptance of the view that chromosomes undergo extensive changes in composition during mitosis necessarily leads to the corollary that the giant chromosomes of the salivary glands of Diptera, which are claimed by geneticists to give a picture of the genetic constitution of the individual in which they occur, differ chemically from the genic material received from the sperm.

E. STEDMAN.

INDUSTRIAL RADIOGRAPHY

Handbook of Industrial Radiology

By Members of the Industrial Radiology Group of the Institute of Physics. Edited by Dr J A Crowther. Pp viii+203 (London: Edward Arnold and Co., 1944) 21s net.

AS Dr Crowther remarks in the introduction to this book, a volume put together as this one is "cannot have the degree of orderly development" that is to be expected in a book written by a single person. Consequently there is a certain amount of overlapping and a noticeable disjointedness which must inevitably occur when a series of discrete papers make up one volume.

The book is timely. During the War the use of X-rays in the inspection and examination of engineering structures has increased enormously, and X-ray inspection has proved itself to be an essential process in engineering development. It is astonishing that such a wide variety of applications of X-ray inspection should have manifested themselves without the appropriate differentiated development in radiographic apparatus. This, of course, may be understandable under war conditions.

The widespread use of X-rays during the War affords a very clear pointer concerning the importance of this branch of science in post-war activity, and there can be no question that the subject will be developed intensively to take its place as perhaps the most important branch of non-destructive testing.

The Radiology Group of the Institute of Physics is indeed to be congratulated on having culled the experience of so many pioneer workers and gathered together their views in the form of these articles. In this book there is very little matter which is not instructive and the collection cannot fail to be of the utmost value to those young scientific men who are now devoting themselves to this branch of technical activity.

It is really undesirable to draw invidious distinctions between papers of such excellence as those collected together in this volume, but special mention must be made of what is perhaps the outstanding contribution by Dr L Mullins—outstanding in the comprehensiveness with which he reviews this subject of industrial radiography. The potentialities of the method, both present and future, are strikingly illustrated by the examples he has collected and described in his article.

Attention should also be directed to another outstandingly useful contribution made by Dr. R. Jackson. In describing his experience in the radiography of heavy steel castings, he provides information of the utmost practical value. Of particular interest is his suggestion of zoning as a method of possible standardization of radiography in relation to the inspection of steel castings. This is a subject of unquestionable importance and one that bristles with difficulties, and Dr Jackson is to be congratulated on the courage with which he has attacked the problem.

There is also a most valuable chapter on physical principles involved in X-ray practice contributed by Mr W J Wiltshire. It cannot be over-emphasized that the would-be industrial radiographer must know something of the physical principles underlying the 'tool' which he intends to use, and Mr Wiltshire has been quite remarkably skilful in putting so much valuable and fundamental information into the short chapter available to him. The first is by no means the least important chapter in the book.

The Institute of Physics has performed invaluable service to industry in having formed a special group for the study and encouragement of industrial radiology. In sponsoring this valuable collection of lectures containing so much practical information it has emphasized that service.

The book under review is described as a "Handbook on Industrial Radiology". Some aspects of industrial radiology are not included, for example, the supremely valuable branch of the subject known as X-ray crystallography. Perhaps "A Handbook on Industrial Radiography" would have been a more generally appropriate title.

V E PULLIN

CONTEMPORARY THOUGHT OF THE RENAISSANCE

Sociology of the Renaissance

(International Library of Sociology and Social Reconstruction.) Translated from the German by W L Luetkiers. By Alfred von Martin. Pp x+100 (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1944) 8s 6d net.

IT is something of an achievement to have written a book, even a small one, about the Renaissance without a mention of Walter Pater. But then he was a gentle creature, whereas Dr von Martin is a little aggressive. Nevertheless, there is much of interest here for the man of science, psychologist and historian, not least because, as the author indicates, the phenomena he describes are of significance far beyond the particular period under review.

Much of the turmoil of those years, the estrangements and the efforts to compromise might well be transported bodily into our experience to-day. In fact, against a background of friction, the essential continuity of the sequence Medievalism-Renaissance-Baroque is exceedingly well brought out, and that alone is worth a great deal. Against it, however, stand a few odd contrasts. An example is the note, referring to the High Renaissance, to the effect that Catholicism was more or less compelled to set the 'here and now' with its stresses and strains, in quasi-opposition to the 'hereafter' with its axiomatic harmony. So far as the *philosophia perennis* goes (and this is supposedly what matters in the present context), such a view is scarcely tenable, since, of all systems, Thomism—whatever its defects—is probably the most comprehensive yet devised, and thus capable of fusing all the various 'knowledge' into something approaching coherence. That it was temporarily decadent is neither here nor there, its potency remained, and in consequence its inherent ability to smooth out the jolts.

Meanwhile, contemporary thought and action were alike obsessed with the boundless possibilities opening up for applied science, art and technics were not seldom practised by one and the same person, notably the peerless Leonardo da Vinci. How bitterly his brother artists complained that he had deserted them for engineering! It was no mere accident that he venerated Archimedes and shunned Aristotle, a point upon which it would be good to have Dr von Martin expound. But there is no mention of it. Leonardo ends almost immersed in numinous rapture over the problem of natural law, while the merry men of the Renaissance carried on until one of the greatest storms in human history had blown itself out.

F IAN G RAWLINS

RONTGEN CENTENARY AND FIFTY YEARS OF X-RAYS

By PROF. J. A. CROWTHER
University of Reading

WILHELM KONRAD RONTGEN was born on March 27, 1845. The discovery of X-rays was communicated by him to the Physico-Medical Society of Wurtzburg in November 1895, a translation of his paper appeared in *Nature* of January 23, 1896. The present year thus marks the centenary of the birth of the discoverer, and the fiftieth anniversary of the epoch-making discovery with which his name is associated. It has sometimes been suggested that the discovery of X-rays was a happy accident, but there is no doubt, from the nature of his preparations, that Rontgen had, as he himself stated, set out to see whether the electric discharge through a gas at low pressure gave out any kind of 'invisible radiation' capable of detection outside the walls of the glass tube in which the discharge was taking place. The discharge tube (an ordinary Crookes tube of the cylindrical pattern, with a flat cathode at one end, and an anode tucked away in a side tube) had been wrapped in black paper, to cut off all the visible glow from the discharge, and a primitive fluorescent screen, consisting of a few crystals of barium platinoeyanide on a piece of cardboard, lay handy on an adjacent bench—barium platinoeyanide being a substance commonly used at the time to detect the invisible rays in the solar spectrum. On exciting the tube by means of a small induction coil to see if the light from the discharge was properly obscured by its black paper wrapper, Rontgen found that this was, indeed, the case, but he also noticed that his primitive fluorescent screen was now glowing brightly. The discovery of X-radiation had been made.

It was as simple as that, but it was not 'accidental', unless it be regarded as a happy accident that Rontgen should have thought it worth while to investigate a possibility so remote from current physical thought that, although research into the physics of the Crookes tube was being actively pursued in some of the leading physical laboratories, no other experimenter had thought it worth while to make the very simple tests involved. Some workers had, in fact, been inconvenienced by the fogging of photographic material kept in the same laboratory as their Crookes tubes, but, finding that the trouble could easily be overcome by storing the material elsewhere, they proceeded with the researches on which they were engaged without further thought or hindrance.

Rontgen showed that the new X-radiation affected a photographic plate, and he was able to take a photograph through the thickness of a stout pine-wood door separating two of his laboratories. He also noticed that a strip of beading, which had been stuck on the door panel with white lead, cast a distinct shadow on the negative, the thin layer of lead being much more opaque to the radiation than the wood itself. Thus the foundations of the science of radiography were laid.

Both for its practical importance, and for its immense value as a tool for further research, the discovery of X-rays ranks high among the germinal discoveries of physics. The power of the radiation to penetrate considerable thicknesses of materials opaque to ordinary light, and to cast shadows of structures

of greater or smaller density concealed within them, caused considerable popular excitement, and had obvious possibilities. The fact that the discovery was first communicated to a medical society has been taken as an indication that Rontgen immediately foresaw its importance in medical diagnosis, though the possibility that he merely took the readiest means of establishing his claim to what was clearly a discovery of first importance cannot altogether be overlooked. However this may be, the new radiation was taken up by members of the medical profession in all countries, in Britain among the first, with a zeal and devotion quite beyond praise. The pioneers among them began work with apparatus little more effective than, and quite as troublesome as, that with which Rontgen made the original discovery. A radiograph of even such an easy subject as the human hand required an exposure measured in minutes. Gradually, however, the insistent demands of the medical radiologists for more and more penetrating power, and shorter and shorter exposures, bore fruit. With the realization that there would be a substantial market for X-ray equipment, engineers became interested in the problem, and the modern diagnostic set is capable of producing excellent radiographs of any part of the human body in a matter of seconds, and with little more trouble to the operator than would be involved in switching on an ordinary electric lamp.

Progress in the interpretation of the radiographs has been equally marked. In medicine, X-rays have evolved from an exciting novelty into a standard routine. Some of the pioneers are with us still, others, we recall, as in duty bound, lost their lives through their devotion to their work, since the dangerous nature of the radiation was not at first realized.

It is not the purpose of this brief article to sketch the story of the evolution of medical radiography, but its recent invasion of the field of preventive and social medicine deserves at least a passing notice. Mass radiography, that is to say, the routine radiography of all workers, has already begun, and will undoubtedly be extended as conditions permit. In such diseases as pulmonary tuberculosis, early diagnosis is nine-tenths of the battle, and the presence of the disease can often be identified by radiography long before any physical symptoms occur to direct attention to it. In a recent survey of some 20,000 operatives, some 1½ per cent were found to be affected, and were sent for treatment. Thus some three hundred workers will owe their escape from serious incapacity, and possibly from a premature death, to this development of Rontgen's discovery of X-rays.

The use of X-rays in the treatment of disease has scarcely made such satisfactory progress as its use in diagnosis. Many malignant growths, sarcomas, carcinomas and the like respond rapidly to the action of radiation, and fade away under its influence as if by magic. For many types of these scourges upon humanity, X-radiation, either alone or accompanied by radium radiation (which, after all, is only a kind of naturally occurring X-radiation), is by far the most hopeful treatment, and no great hospital is complete without a well-equipped and well-staffed radiotherapy department. It must be confessed, however, that there is as yet an uncertainty about the action of the rays which is very tantalizing. Complete success appears to be so near, and yet continues to elude us. The action of the X-rays on tissue cells, whether healthy or diseased, is, it must be

understood, always destructive, the possibility of using X-rays to cure disease rests on the fact that malignant cells are, on the whole, less resistant to the action of the rays than healthy tissue. Some of our troubles are undoubtedly due to the difficulty of administering a lethal dose to the malignant growth without damaging the surrounding healthy tissues. This is, primarily, a problem in physics; and the appointment of qualified physicists to the staff of the radiotherapy departments, which is now becoming general, will undoubtedly lead to some solution in due course. Probably a more vital handicap has been that little or nothing was known of the way in which the radiation exerted its destructive powers on the cell. Treatment, therefore, has had to be largely empirical. Recently, however, thanks to ingenious co-operation between physicists and cytologists, it begins to look as if a breach had been made into the problem. If so, not only may methods of treatment gain in certainty, but also X-rays may add a new chapter to our knowledge of the living cell, as they have already added more than one to our knowledge of the atom.

Industry, on the whole, was slower to grasp the utility of X-rays than the medical profession. Some small amount of radiographic testing of materials for hidden defects was carried out during the War of 1914-18, mainly in connexion with aeroplane construction, in which the importance of ensuring the complete soundness of every part justified the very considerable skill and trouble involved in making radiographs with the comparatively primitive apparatus then available. Gradually, however, the value of X-rays as a non-destructive method of investigating the soundness of castings, weldings and other industrial products received fuller recognition, and the number of industrial radiologists, in this second World War, must very greatly exceed that of medical radiologists. The demands of industry, even more effective than those of medicine, since they are backed with much larger capital, have resulted in still greater advances in the design of X-ray apparatus. Million-volt X-ray tubes, enclosed with the high-tension generator which feeds them in a single unit weighing three-quarters of a ton, are now on the market, and in heavy industry (in which they are mainly employed) are regarded as quite portable. With such an outfit, successful radiographs can be made through a 6-in. steel plate, and, under suitable conditions, cracks or flaws of no more than a tenth of an inch in thickness can be detected with certainty.

To one who began X-ray work not many years later than Röntgen's original discovery, the contrast between one of these huge but obedient 'genii of the lamp' and the miscellaneous and extremely temperamental assortment of physical apparatus with which Röntgen first revealed the existence of X-rays (and which, with a few minor improvements, served experimenters for the next twenty years or so) is astounding. By their creation, applied science has gone far to repay the debt which it owes to pure science for the discovery of the radiation. When times are again favourable, pure science will no doubt respond by using these powerful tools to make still fresh discoveries. Nor has the limit yet been reached. A two-million volt tube, some 10 ft. long, is now in operation, while another carries (for a millionth of a second) a current of 2,000 amperes at 300,000 volts, and has been employed for making instantaneous radiographs of the passage of a high-velocity shell through a 1½-in. armour plate.

Still higher voltages, accompanied by still greater penetration and power in the radiation, is promised by a new type of generator, working on entirely novel principles, which has recently been constructed in the United States. From this machine, which has been christened the 'betatron', X-radiation at energies up to thirty million volts can be obtained. When it is remembered that the most penetrating radiation from radium is equivalent to X-radiation at only two million volts, it will be realized that the betatron carries us into an entirely novel and unexplored region of the X-ray spectrum. Such radiation will penetrate not merely the outworks, but also the central citadel or nucleus of the atom, and its effects, particularly in radiotherapy, are quite unpredictable. They may be beneficial, or disastrous, but it is evident that we cannot afford to leave them unexplored. It is greatly to be hoped that the various bodies in Great Britain, whether Governmental or voluntary, interested in radiotherapeutics, and particularly in cancer research, will make the necessary provision for British research workers (who have already done so much, often with painfully inadequate resources) to play their part in the quest.

It is natural, in tracing the consequences and developments of Röntgen's discovery, to dwell first on its more immediate applications. X-radiation was, however, one of those germinal discoveries, which are at least as important for the new knowledge which they make possible as for their direct utility. Coming, as it did, a year or so before the complementary discovery of the electron by Sir J. J. Thomson, it opened the way to entirely new regions of experimental research, including the structure of atoms and molecules, and the nature of radiation itself. It may well be that when the final balance comes to be struck, the importance of X-rays as a means of winning fresh knowledge may be judged to outweigh their more directly utilitarian merits.

A knowledge of the nature of the rays was a necessary preliminary to their intelligent application in further research. The true explanation was put forward by Stokes within a few months of Röntgen's discovery. He suggested they were electromagnetic pulses produced by the sudden stoppage of the electrified particles carrying the discharge, and therefore of the same nature as light (though probably of much shorter wave-length). So far, however, did Röntgen's discovery stand apart from the general trend of the physical thought of the time, that there was an interval in which some physicists were inclined to associate the radiation with the vivid fluorescence of the glass walls of the Crookes tube, which is an invariable accompaniment of the electric discharge. Becquerel was led to investigate whether X-rays were also given off by naturally occurring fluorescent materials. Uranium was one of the substances tested, and thus the natural radioactivity of uranium was discovered. The isolation of radium, by the Curies, followed. Thus the whole science of radioactivity may be regarded as a direct offspring, though perhaps an illegitimate one, of Röntgen's discovery.

Although Stokes's suggestion was soon generally accepted, and was supported by Barkla's demonstration that X-rays, like light, could be polarized, progress was at first slow. Such evidence as there was indicated that the wave-length of the radiation must be of the order of one ten-thousandth of that of ordinary light, and attempts to apply the diffraction

methods used in determining optical wave-lengths seemed almost hopeless. It was not until 1912, when Laue suggested that the regular spacings of the atoms in a crystal might serve as a naturally occurring diffraction grating for X-rays, that real progress was made. The suggestion was immediately verified by Friedrich and Knipping, and in the following year W. L. Bragg, by a most ingenious combination of crystallography and optical theory, succeeded in determining simultaneously the grating constant of a rock-salt crystal, and the wave-length of the X-radiation employed.

This achievement has a double significance. If the spacing of the atoms in a crystal is known, we can, from diffraction measurements, determine the wave-length of the radiation impinging upon it, and thus obtain an X-ray spectrum. Conversely, if the wave-length of the radiation is known, we can deduce the spacings or lattice constants of the crystal. Thus, in the X-ray spectrometer, crystallography has found a most powerful research tool which has given quite a new impetus to this rather old-fashioned science. The practical importance of X-ray crystallography in metallurgy can scarcely be over-estimated. Since each chemical compound has its own unique set of lattice constants, it is possible to identify, not merely the elements present in a given substance (a task for which ordinary spectroscopy or chemical analysis will suffice), but also the actual compounds which these elements form with each other, and the temperatures at which these compounds form, or at which they disappear. When the field has been fully surveyed, and the X-ray crystallographic index which is already in active preparation is completed, it will be possible to identify any crystalline compound in an alloy or mixture by X-ray analysis. Nor is the field limited to true crystals. Many long-chain organic substances are sufficiently regular in their make-up to act as X-ray gratings, and much information, valuable both on the theoretical and the industrial side, has already been obtained (to quote only one example) on the structure of the fibres used in the weaving of textiles. To understand why substances behave as they do, in terms of the position of the atoms within them, is the first step in a scientific search for new and better materials, and X-ray crystallography seems destined to play a part in industry even more important than in radiography.

To attempt to survey the part played by X-rays in atomic research would involve the recital of the greater part of the history of that part of the subject dealing with the structure of the electron atmosphere which surrounds the central nucleus and on which most of the chemical and physical properties of the atom depend. Most of our exact knowledge—and it is very exact—of the arrangement, or to be more precise, the energy-levels, of the electrons in the atom, is derived from X-ray data. It may be recalled that Moseley's early survey of the characteristic X-ray spectra given out by the elements provided the first clear demonstration of the fundamental importance of the idea of atomic number, that is to say, the charge upon the atomic nucleus as opposed to the atomic weight, which was shown to be of only secondary importance. It is interesting to notice that Moseley's results showed that four elements still remained to be discovered, and that two of these have since been identified by their X-ray spectra. It may also be mentioned that the most accurate determinations of the two fundamental physical constants, the charge on an electron and Planck's

constant, are, in all probability, those derived from X-ray measurements.

The temptation to moralize on the history of the discovery of X-radiation, and its consequences, is strong, but the task may be left to the reader. Nature is full of surprises, and it is not always the most obviously desirable researches which yield the richest harvest. The lone experimenter who is prepared to follow his own inspiration, even if it seems to lead him away from the main current of research, has often played an important part in the progress of science, and pure science in particular, and society in general, owe much to the inspired curiosity of Wilhelm Konrad Rontgen.

DIFFRACTION METHODS IN MODERN STRUCTURAL CHEMISTRY

IN the Tilden Lecture delivered before the Chemical Society on January 18, Prof. J. M. Robertson outlined first the scope, limitations and possible future developments of the X-ray and electron diffraction methods, and then went on to consider the nature and lengths of bonds with particular reference to the results of recent diffraction studies. The emphasis throughout was on organic structures, as would be expected from one who has contributed more than any other single worker to our knowledge of the precise crystal structures of organic compounds.

In comparing the electron and X-ray diffraction methods, a number of points were brought out. The great value of the former is that it is applicable to gases and the vapours of easily volatile substances, which cannot conveniently be studied by the X-ray method. In this sense the two methods are complementary. We might add that, as regards inorganic compounds, they are complementary in another sense. In general, the same finite molecules exist in the vapour as in the crystals of an organic compound, but this is not usually so in inorganic chemistry. Electron diffraction studies of the vapours of many metallic salts and of some of the compounds of non-metals give information about the structures of molecules which do not exist in the crystalline material.

A comparison was made of the nature of the experimental data obtainable by the two methods and of the ways in which they are interpreted. To the eye the electron diffraction photograph shows merely a number of rings on a background of decreasing intensity, and their positions and intensities are estimated visually. The X-ray photograph from a single crystal, on the other hand, shows a large number of discrete spots, and the positions and intensities of these can be determined with considerable accuracy. This apparent advantage of the X-ray method is, however, offset by two complications. First, the molecules in the gas scatter independently of one another and they are oriented in all possible ways. This makes it possible to calculate the diffraction effects to be expected for any given molecular model and to compare them with those observed, the parameters in the model being varied until agreement is obtained. In the case of diffraction by a crystal, this cannot be done. In the crystal the molecules are definitely oriented with respect to one another, so that not only has the molecular model to be varied

but also the mutual orientations, and hence the intermolecular distances. Secondly, it is usually impossible to utilize more than a small fraction of the X-ray data on the photographs. Apart from purely technical difficulties, which can eventually be overcome, there is a complication inherent in the X-ray method, namely, that the structure amplitude F_{hkl} corresponding to a particular reflexion is a complex quantity with an amplitude and a phase constant. From the observed intensity we can in general determine only the amplitude. Except in certain cases, therefore, it is necessary to work by a trial and error method based on a probable molecular model which is progressively refined as the structure-determination proceeds. The difficulty of determining phase constants may sometimes be overcome by making comparisons of data from isomorphous compounds or by studying crystals containing heavy atoms. If we assume complete ignorance of phase constants, then all the X-ray data are summarized on a Patterson vector diagram which is directly derived from the observed intensities. An analogy was drawn by Prof. Robertson between the Patterson method for X-ray diffraction and the radial distribution method for electron diffraction. Apart from the difficulty of interpreting Patterson diagrams, owing to the overlapping of peaks, there is the more fundamental difficulty that the same vector diagram (and hence the same X-ray diffraction pattern) may arise from different arrangements of atoms. The discussion of the uniqueness of the solutions of diffraction problems may appear to some chemists rather academic, especially as Prof. Robertson emphasized that a structure must always be consistent with all the other available physical and chemical evidence. However, while it is true that in the case of simple structures there is seldom any doubt as to the correct interpretation of the data, it is important, as the compounds studied become more and more complex, to re-examine the fundamental theory of all methods of interpreting diffraction data.

When discussing possible future developments, Prof. Robertson emphasized the need both for making fuller use of the experimental data and for improving its range and quality. He pointed out that many of the difficulties now encountered in making precise analyses are not fundamental, "and there is no doubt that they can be overcome, largely by the proper planning and organisation of the research, which will have to be on a fairly large scale". Although hopeful that diffraction methods will eventually give information about the positions of hydrogen atoms and about electron densities in bonds, he was careful to indicate some of the difficulties of interpreting the finer details on electron-density maps. On the whole, it would seem advisable to defer drawing conclusions from two-dimensional electron-density projections, and possibly to make detailed studies of the effect of temperature on electron-density distributions in selected crystals using sections through three-dimensional summations, in order to discover the effect of the thermal movements of the molecule as a whole and of different parts of the molecule relative to one another. More emphasis might have been placed on an essential difference between electron and X-ray diffraction, namely, that the nuclei are more effective than the orbital electrons in scattering high-speed electrons, whereas the scattering of X-rays is due to the orbital electrons alone. It is difficult to see how the electron diffraction method in its present form can provide information comparable with the

electron-density maps derived from X-ray studies of crystals. Also, just as the thermal vibrations in solids result in the blurring of these maps, so the greater flexibility of some molecules in the vapour state makes it difficult, or even impossible, to obtain a complete picture of the molecule by the electron diffraction method. For example, the Sn-I distance in SnI_2 can be determined, but not the I-Sn-I bond angle. Provided the molecule possesses sufficient rigidity, however, quite complex structures may now be studied by the electron diffraction method, as shown by the recent work on pyrylene, diphenylene and tri-(phosphonitrile chloride).

Diffraction methods not only provide information about the general configurations of molecules but also they lead to accurate determinations of interatomic distances and inter-bond angles. The X-ray method, of course, gives data on intermolecular as well as intramolecular bonds, and although the weak van der Waals bonds are of comparatively little interest to the chemist, much valuable information about hydrogen bonds has been obtained from studies of crystals. A feature of modern structural chemistry is the detailed analysis of data on bond-lengths with the object of discovering more about the nature of the bonds. At one time 'chemical' bonds were regarded as either ionic or covalent, and in the latter case as single, double or triple bonds. The present view is that all bonds, other than those between atoms of the same element, have some ionic character and also that bonds intermediate between single and multiple bonds exist in many molecules. Bonds of these intermediate types are described in terms of resonance between structures with different arrangements of bonding electrons.

Prof. Robertson discussed the 'order' of carbon-carbon bonds. The C-C distances for pure single, double- and triple-bonds are well established, 1.54 Å in diamond, 1.34 Å in ethylene and 1.20 Å in acetylene. Assuming 50 per cent double-bond character in benzene ($\text{C-C} = 1.39 \text{ Å}$) and 33.3 per cent in graphite ($\text{C-C} = 1.42 \text{ Å}$), Pauling, Brockway and Beach constructed a curve relating percentage double-bond character to bond-length, from which can be estimated the amounts of double-bond character of other bonds with lengths between 1.54 and 1.34 Å. The more detailed calculations of 'bond order' which predict minor variations in length among the bonds in molecules such as naphthalene and coronene cannot yet be checked as the differences are of the same order of magnitude as (or less than) the present experimental errors. This illustrates the need for more precise determinations of interatomic distances. On the other hand, there appear to be some abnormal bond-lengths which cannot at present be accounted for theoretically.

Dealing with bonds between unlike atoms, Prof. Robertson mentioned the recent revisions of certain of the Pauling-Huggins radii, so long adopted as the basis for discussions of interatomic distances. Observed distances which were less than the sums of these radii were considered exceptional, and elaborate explanations in terms of partial ionic character and partial double-bond character have been put forward. With the new (higher) values for the covalent radii of nitrogen, oxygen and fluorine, many bond-lengths are now seen to be appreciably less than the sums of the appropriate covalent radii, even where there is no likelihood of partial double-bond character. The empirical relationship of Schomaker and Stevenson attributes these differences to the ionic character

of the bond, and uses the electronegativity coefficients of Pauling to correct the sums of the Pauling-Huggins radii. In other words, the fact that bonds are shorter than the sums of the true covalent radii is on this later view assumed to be due in many cases to the partial ionic rather than the partial double-bond character of the bonds. In view of the importance now to be attached to Pauling's electronegativity coefficients in discussions of bond type, it is well to remember that our difficulties in this field are an indication that we have not so far solved one of the most complex and fundamental problems in chemistry.

The early electronic theory of valency assigned electronic formulae to many molecules, but offered no explanation either of the observed inter-bond angles or of the differences in properties between atoms with the same number and arrangement of valency electrons. As regards bond angles, it was necessary to find a way of investigating the 'group properties' of a number of valency electrons, and this problem has been solved to some extent by the methods of wave-mechanics. We are still, however, far from being able to account for the chemical properties of an atom. Although elements of a group such as the halogens, all with similar sets of outermost electrons, have certain characteristics in common, nevertheless each halogen has a distinct 'individuality' and the changes in properties do not all run parallel with the increase in size (or atomic number). Thus although the properties of the atoms are to some extent determined by their outer electronic structures, the finer differences between atoms which are similar in this respect will not be explained until we are able to take into account the effect of the nuclear charge and the remaining shells of electrons.

Until we find some theoretical way of specifying these distinctive chemical properties in terms of the structure of the isolated atom, they can only be estimated from the way in which the atom interacts with other atoms. The use of the electronegativity concept represents an attempt to deal with the problem in this way. The electronegativity coefficients are derived from experimental observations on the interactions between atoms, namely, from bond energies. The new empirical relation connecting actual bond lengths with true covalent radii and electronegativity coefficients simply expresses the fact that the difference between the length of a bond $A-B$ and the arithmetic mean of $A-A$ and $B-B$ is related to the difference between the energy of the bond $A-B$ and the arithmetic mean of the energies of the bonds $A-A$ and $B-B$. Some relationship is obviously to be expected, it was not apparent earlier because incorrect radii had been assigned to three of the most electronegative elements. It is, however, relevant to inquire whether the same relationship should apply to all pairs of dissimilar atoms, that is, whether the nature of a bond is the same for any pair of atoms with a particular difference in electronegativity regardless of the absolute values of the electronegativity coefficients. It will also be necessary to inquire into the general validity of Pauling's curve relating the percentage ionic character of a bond to the difference between the electronegativities of the atoms, a curve based on the dipole moments of the halogen halides. For example, are we justified in assuming that two electrons are shared in exactly the same way between two fluorine atoms as between, say, two carbon atoms, and is the relation between bond type and electronegativity the same

for atoms in a horizontal row as in a vertical column of the Periodic Table? The difference between the electronegativity coefficients of carbon and silicon is greater than that between those of, say, carbon and nitrogen, yet Pauling quotes the carbon-silicon distance in tetramethyl-silane as an example of the additivity of covalent radii.

In order that future discussions of the nature of bonds shall be put on a sound basis, it is to be hoped that some of these points and some of the experimental data will be critically examined. The results are of great general interest to many chemists, of whom relatively few may be in a position to criticize the conclusions reached by the specialist. This is one of the dangers attending the increasing specialization which is a characteristic of modern science. Perhaps there is still room for a Carneades, of whose function Boyle (in "The Sceptical Chymist") wrote, "that having thus drawn the chymists' doctrine out of their dark and smoky laboratories, either judicious men shall henceforth be allowed calmly and after due information to disbelieve it, or those abler chymists will be obliged to speak plainer than hitherto has been done, and maintain it by better experiments and arguments".

A. F. WELLS.

THE SCIENCE OF PLANT BREEDING

By D. LEWIS

John Innes Horticultural Institution

THAT breeding is an art and not a science is an opinion frequently expressed by many who are concerned with plant and animal improvement. Whatever they have meant by art in this generalization, it appears that, in their hands, breeding is mainly unscientific. It is certain, however, after reading Dr Harland's report on cotton breeding in Peru¹ that, in his hands, breeding is truly scientific and as such can give good results quickly. It is scientific because measurements of the relevant characters were his standards for selection, and because genetical principles were the guide in calculating the number of plants required, and in deciding the type of breeding. Therefore, he did not rely upon the hazards of hit-and-miss intuition of the art side of breeding.

Tangurs, originating as a chance seedling in 1908, has been the main variety of cotton grown in Peru since that date. It was originally of excellent quality and yield; but subsequent contamination from crossing and seed mixing with other stocks has caused much deterioration. In 1940 Harland had the task of reviving and improving its characteristic qualities, and in three years he has increased the mean fibre length by $\frac{1}{8}$ in. above the mean for commercial *Tangurs*, and has also made improvements in ginning percentage, boll weight, colour and yield. So that in 1943, 2,100 acres were planted with his improved seed.

How was this remarkable achievement brought about? The taxonomic position and origin of the variety *Tangurs* are first considered, since these are prerequisites to any scientific breeding programme. *Tangurs* has most of the characters of *Gossypium barbadense* with the early maturity of *G. hirsutum*, as a result of which previous Peruvian workers believed it to be a hybrid. But some early work of Harland showed that it is pure *barbadense* and that the early maturity arose by selection due to associa-

tion with *hirsutum* in mixed plantations and not to intercrossing between them

The objectives of the work, nine in number, included improvement in such characters as yield, fibre-length, colour and disease resistance. In a description of his work, Harland examines and criticizes the orthodox pure-line breeding, which has been slavishly adhered to by many breeders. The advantage of a pure line is the uniformity of the commercial product, and he concluded that the value of this has probably been overrated, at least in cotton. For example, fibre-length from single seeds was found to be almost as variable as that from commercial bales made up from plants of diverse genotypes. On the other hand, the disadvantage of early fixation of the genes (favourable and unfavourable) has sometimes been overlooked, as effective selection is then confined to the original plants and the first selfed generation. In the past, far too few original plants have been used to provide sufficient genetic diversity for selection. As Harland shows, it is necessary, in theory, to start with 1,024 strains in order to obtain eight strains which will be above the average in seven characters at the end of selection. Furthermore, when a good pure line has been found, it is not necessarily good in the majority of the environments that any good commercial plant is likely to encounter. Lack of plasticity does not allow the slight adjustments by natural selection which would occur in a mixed population.

For the purpose of maintaining a certain degree of diversity from which further selection would be possible, and also for obtaining effective results quickly, Harland abandoned pure-line breeding. No self-fertilization was practised, and mixtures of strains were propagated. Selection was started on 22,000 boll samples, each taken from a single plant, from various commercial fields. A first selection based on all characters rejected all but 2,863 of them. Ten plants of each selected strain were grown, and bulk samples of the ten plants were examined for all characters. This not only saved much labour in single-plant selection, but it also eliminated heterozygotes which, although themselves good, produce bad offspring by segregation. Forty-one strains survived these bulk tests, which after single-plant selection provided two hundred plants for progeny testing. Two thousand seedlings were raised from these, and after subjecting them to bulk and single-plant selections forty-three strains finally remained. Ten of these were propagated, giving sixty-three strains in the following year. These were mixed together and distributed as commercial seed.

Thus Harland has been able to restore the good qualities of the cotton plant in Peru, and indeed to add further improvement in a very short time while retaining genetic diversity for further selection. In grasses, mixed strains have been bred at the Welsh Plant Breeding Station and utilized with success². Hitherto it has been thought that, in respect of the requirements of variation, pasture crops were different since less uniformity is necessary than in more highly specialized crops, but in view of the success in cotton the mixed strain is worthy of trial in other plants. It should be especially useful in crop plants which suffer from pests and diseases in epidemic form, when genetic heterogeneity may prevent widespread destruction.

OBITUARIES

Prof J. K. Catterson-Smith

JOHN KEATS CATTERSON-SMITH, professor of electrical engineering at King's College, University of London, was born on December 27, 1882, and died on January 25, 1945. His father was a well-known artist who became head of the Birmingham School of Art. The son received his early education at the City of London School and then entered the University of Birmingham. Here he held the Bowen research scholarship during 1902-4 and published the results of investigations on transformers, direct current motors and rotary converters. After three years at Siemens Dynamo Works, Stafford, he returned to academic life as lecturer in electrical engineering, and after a period at the University of Liverpool became chief assistant to Prof Silvanus Thompson at the City and Guilds of London Technical College, Finsbury.

Between 1904 and 1914 Catterson-Smith published a number of papers on the starting of motors, on commutation in direct current motors, on harmonics in three-phase networks and on the manufacture of large turbo-alternators. He also contributed to the theory of transformers, induction motors and cascade motors. In 1915 he joined the Navy in the R N V R and was sent to help enlarge the wireless station at Demerara. Upon returning to Portsmouth he took part in the new developments of thermionic radio apparatus, especially in connexion with submarines. He served at sea in submarines and was promoted to lieutenant-commander. In some of the radio and supersonic developments he and I collaborated at Portsmouth and Toulon, and in particular we solved the problem of synchronizing an electric motor with a tuning fork, in preparation for facsimile transmission. Some of this work was done at Finsbury, after he had returned to his old post. Here, also, he published papers on audio-frequency amplifier design and on the theory of intervalve transformers.

In 1918 he married Miss Rita Thom and settled down to academic life again at Finsbury, but in 1923 he was offered the professorship of electrical technology at the Indian Institute of Science, Bangalore, where Sir Martin Forster was then director. At Bangalore he spent several ardent years building and equipping new laboratories, installing heavy-current plant and inaugurating a wireless research laboratory. He founded the Institute journal *Electrotechnics* and probably wrote most of it during its infancy. He and his wife, I have been told, assisted greatly in promoting the social life of the Institute.

In 1930 Catterson-Smith was appointed professor of electrical engineering at King's College, London, in succession to Ernest Wilson. Among his original researches of this period are those on the paralleling of large transformers, and on the theory and measurement of positive and negative sequence components of three-phase currents and voltages in three-wire unbalanced networks. Then came the War and the College moved to Bristol.

In the domain of electrical engineering Catterson-Smith will be remembered for the originality of his experimental work, for the careful workmanship of the apparatus he constructed and for his lucid exposition of what may be called the physiology of electrical machines—which ranged from large turbo-alternators to electric kettles and electric toys. His was one of those minds that restlessly endeavoured

to improve the operation of every machine encountered, his mental processes consisted in first gaining a thorough insight into the operation of the existent machine and then applying remedies to the weaknesses disclosed. This passion for improving and inventing continued to the end of his life. For example, during the last two years he had been working on an improved electrical tele-mechanism of great ingenuity.

In Catterson-Smith there was an unusual and happy blend of art and science. His artistic instincts called for craftsmanship and appropriateness, his scientific instincts for accuracy and efficiency. These qualities imbued all his work. In addition, he possessed a personality of great friendliness and charm. No wonder he gained the affection of all his students and colleagues.

W H ECCLES

Prof James Muir

By the death, on February 17, of Prof James Muir, emeritus professor of natural philosophy in the Royal Technical College, Glasgow, there has passed a great teacher and a man singularly devoted to science and to the quest of knowledge for its own sake.

Dr Muir was born in 1875, and his early interest in science was stimulated by his education at Allan Glen's School, Glasgow. On leaving school, he entered his father's business, but the influence of his school training led him to consult Prof James Blyth, on whose advice he entered his evening class at the Technical College. Thus began a connexion with that College which was to remain unbroken throughout his life.

Muir graduated BSc in 1896 at the University of Glasgow, with special distinction in engineering and astronomy, and DSc in 1902, having obtained the associateship of the College in mathematics and physics in 1897, in which year he was awarded an 1851 Exhibition Scholarship at Cambridge. His researches at Trinity College, under Prof Ewing, into the effect of temperature on recovery from overstrain were published in the *Proceedings of the Royal Society*, and he was awarded the BA degree of Cambridge, followed in 1904 by the MA. Returning to Glasgow, he became chief assistant to Prof Blyth, and then assistant to Prof Andrew Gray at the University of Glasgow.

In 1906, on the death of Prof Blyth, Dr Muir succeeded to the Freeland chair of natural philosophy in the Technical College, Glasgow, and he entered upon his duties with a boundless enthusiasm which continued during the thirty-two years which ended with his retirement in 1938.

Prof Muir always gave foremost place to his teaching and to the interests of his large classes of day and evening students. Nevertheless, he found time to use to the full the resources of his department in conducting many valuable researches on behalf of the industrial firms of Glasgow, and during the War of 1914-18 these researches were directed to the service of the country. He willingly and enthusiastically entered into any movement for promoting the welfare of the College, such as the work of the *College Research Journal* and the re-arrangement and cataloguing of the founder's library.

Prof Muir will always be remembered as a great teacher whose constant aim was to induce his students to think for themselves, to abhor anything slipshod

and to enjoy hard work as he himself enjoyed it. The sincerity and love of truth shown in his scientific work was carried into his everyday life, 'he nothing common did or mean', nor could he compromise upon ethical principles. His students, like all his immediate colleagues, grew to look upon him with affectionate respect; they found him always approachable and eager to share and stimulate their interests. On his retirement, as an expression of their admiration and regard, his former students and colleagues founded and endowed the James Muir Prizes in natural philosophy, and presented to the College the fine portrait by David S Ewart which now hangs in his old lecture room.

Dr Muir's tastes were simple and his wants were few. From his student days he had a great love of the Scottish hills, and friends have most pleasant memories of holiday climbs in his company. At the time of his death he had prepared the manuscript of a text-book on physics and he was engaged on a memoir of the founder of the College. Prof Muir was unmarried and is survived by three sisters.

Mr F R. S. Balfour, C.V.O.

By the death of Frederick Robert Stephen Balfour on February 2, arboriculturists and horticulturists have lost a valued friend and counsellor. Though primarily an arboriculturist he was also a keen naturalist and a true lover of all kinds of plants. He had the advantages of having the means of travelling and of inheriting from his mother the beautiful estate of Dawyck in Tweeddale which possessed a number of interesting and historical trees. In later life he had important business interests in the City of London, and it was probably his business ability which led him to include experimental forestry plots on a large scale at Dawyck.

Balfour was born on March 11, 1875, and was educated at Loretto and Trinity College, Oxford. In his early days he spent four years on the Pacific coast of North America, and, although he was greatly interested in all the plant and animal life, it was the trees which captivated his imagination. He was familiar also with the trees of eastern Canada and the north-eastern States and had a working knowledge of the wonderful forests of south Chile. He became, therefore, a recognized authority in Great Britain on American trees, especially conifers. When he returned to Scotland he developed the collection of North American trees at Dawyck, introducing several species for the first time, his favourite being the rare *Picea Breweriana*, and trying out practically every species which could be expected to survive. In addition to his New World conifers he had also a collection of the more hardy Asiatic species mostly introduced by E H Wilson, whose second expedition to China he helped to finance. He had a great knowledge of British birds and was proud of his notable collection of foreign ducks and pheasants. From the economic point of view his most important contribution to silviculture concerned the trial of promising, but as yet unfamiliar, species under forestry conditions or on the mountainside.

Balfour's published communications are scattered throughout a number of journals; his account of David Douglas, his "History of Conifers in Scotland" which covered a wide field, and a paper read recently before the Linnean Society on Archibald Menzies being perhaps the most noteworthy.

As a member of the Home Grown Timber Com-

mittee, Balfour was sent to France as liaison officer to the French Government during the War of 1914-18, with reference to the supplies of timber. He was one of the founders and remained a most active member of the Roads Beautifying Association, being at his death chairman of the technical sub-committee. His wide love of plants was shown by his zeal in supplying material for figuring in the *Botanical Magazine*.

Balfour had been a fellow of the Linnean Society for many years and had served on the Council of the Royal Horticultural Society, the latter bestowing on him in 1927 its highest award. He had been a member of the King's Bodyguard for Scotland since 1900 and was made C.V.O. in 1944. His other interests included history, architecture and music, he himself possessing a fine baritone voice. But no notice of him would be complete without emphasis on his exceptional courtesy and charm, which were due largely to his understanding and sympathy and to

the genuine pleasure it gave him to do good to his fellow-man.
A D COTTON.

WE regret to announce the following deaths.

Mr F Bligh Bond, formerly director of excavations at Glastonbury Abbey, on March 8, aged eighty.

Mr. G V Boys, secretary of the Institution of Naval Architects since 1935, on March 15, aged fifty-one.

Sir Thomas Lewis, CBE, FRS, physician-in-charge of the Department of Clinical Research at University College Hospital, London, on March 17, aged sixty-three.

Mr P. W. Paget, a technical assistant of Marconi during his early work in England from 1896 onwards.

Prof Stanislaw Zaremba, sometime professor of mathematics in the University of Cracow, and a member of the Polish Academy of Science, aged eighty-one.

NEWS and VIEWS

Chair of Biochemistry at Sheffield

Prof. H. A. Krebs

THE University of Sheffield has conferred on Dr H. A. Krebs the title and status of professor of biochemistry in recognition of his eminence in the world of science. Dr Krebs was awarded the degree of M.D. (Hamburg) in 1925 and that of M.A. (Cambridge) in 1935. He held the post of research assistant at the Kaiser Wilhelm Institute for Biology, Berlin-Dahlem, during 1926-30 under Prof Otto Warburg. After further experience in Germany he became a Rockefeller research student in the Biochemical Laboratory, Cambridge (1933-34), demonstrator in biochemistry at Cambridge (1934-35) and lecturer in pharmacology at Sheffield (1935-38). In 1938 he was appointed lecturer in charge of the newly created Department of Biochemistry in Sheffield, and attracted to his department research workers from both Europe and America. He is a naturalized British subject, and during the War he has given valuable service in connexion with diet and nutrition. His main contributions to biochemistry are in the field of intermediary metabolism. He showed that the synthesis of urea in the mammalian liver is catalysed by ornithine. This observation led to the formulation of the 'ornithine cycle', according to which ornithine, citrulline and arginine are intermediate stages in the synthesis of urea. His work on the oxidation of carbohydrate in muscle showed that this metabolic process, too, is a cyclic one (known as the 'Krebs cycle'), where a series of organic acids arises periodically.

Prairie Regional Laboratory, Canada

Prof R. K. Larmour

PROF. R. K. LARMOUR, professor of chemistry in the University of Saskatchewan, has been appointed director of the Prairie Regional Laboratory which is to be built in Saskatoon by the Canadian National Research Council. Prof Larmour served in the War of 1914-18, and following his return from overseas, he graduated from the University of Saskatchewan and carried out postgraduate work in the University of Minnesota, where he was Shevlin fellow. He joined the staff of the University of Saskatchewan in 1927

and has remained there ever since except for a short period when he occupied the chair of milling industry at a mid-western American university. Dr Larmour has a high reputation in the field of grain research. The Prairie Regional Laboratory will be concerned primarily with investigations into the utilization of agricultural crops. It will be provided with facilities to undertake all phases of laboratory and pilot-plant investigations in this field.

Colonial Development and Welfare Bill

THE essential feature of the new Bill dealing with Colonial development, which should be of interest to administrators, scientific men and technologists, and all who are concerned with the welfare and advancement of the British Colonial possessions, is that it represents a notable extension of the Colonial Development and Welfare Act of 1940. The extension concerns both the annual provision of funds and the period over which they will be available. Put briefly, whereas the Act of 1940 made available a sum of £5,000,000 per annum for development and £500,000 per annum for research, until 1951, the new Act makes available, unless 'Parliament otherwise determines', a sum of £120,000,000 for all purposes during the period 1946-56. A commendable elasticity, which all who are responsible for new schemes whether of research or development will appreciate, is a feature of the new enactment. Thus it is explicitly stated that no time limit is imposed on schemes of research and investigation and up to £1,000,000 can be spent on such schemes in any one year. For all purposes, up to £17,500,000 may be expended in any one year.

Few will disagree with these measures. Substantial help for the Colonies has been long overdue. Now, it is reasonable to hope that definite schemes may not only be planned and set in motion but also actually carried through to fruition. Readers of *Nature* are already familiar with the very diverse developmental, constructional, sociological and research projects which require and are receiving attention under the Colonial Development and Welfare scheme. In particular, it may be pointed out that members of university staffs and of the teaching profession in Britain, as also in the Dominions and in the Colonies,

have a very real responsibility for the successful outcome of the new Bill. The key to success can be stated in a single word: personnel. Personnel for administration, technology and research. The production of suitable candidates for the many and varied jobs is the task of the schools and universities. In these days it is one beset with difficulties, and it may well be that some years must elapse before suitable staff for some of the research posts, for example, in biology, can be produced. But the task lies clearly before us. The sooner we begin, the better for the welfare of the British Colonies.

Science, Poetry and Religion

THREE lectures delivered by Mr Geoffrey Hoyland at Woodbrooke Summer School in 1944 have now been printed as a challenging and picturesquely written booklet entitled "The Tyranny of Mathematics" (S.C.M. Press, Ltd., 56 Bloomsbury Street, London, W.C.1. Pp 52. 1s 6d. net). Mr Hoyland's theme is the age-old dichotomy between the emotional and the rational approach to human problems, but his treatment is fresh, partly owing to his vivid style, and partly because it is unusual to find a religious apologist with a good knowledge of science and mathematics. It is not possible here even to summarize his arguments and exhortations. His conclusion, briefly, is that since the Renaissance, and particularly since Newton and Leibniz added the weapon of the calculus to the armoury of the man of science, we have worshipped at the analytical shrine of mathematics, to the exclusion of the true gods of poetry and religion, which, with science as their handmaid, can't alone reveal to us the whole truth about the universe. "If our sick world is to be saved the lover and the poet must take control."

Few men of science will go the whole way with Mr Hoyland, preferring to believe that a constantly adjusted partnership between the emotional and rational elements in life, rather than the supremacy of either over the other, is the most fruitful treatment of the dichotomy (and indeed the only one that would justify the use of the word 'symbiosis' in the subtitle), but many will be stimulated by this keen analysis of the problems involved, and enjoy the colourful language in which it is couched.

Cultivation of Rhubarb

RHUBARB is one of the oldest cultivated plants, for its history in China, its native home, dates back to almost 3000 B.C. At first it was grown solely for the medicinal properties of its roots and was introduced into England from Siberia on that account some three hundred years ago. Later, interest developed in the edible properties of the leaf stalks, but it was not until the nineteenth century that plantings of rhubarb for culinary purposes became widespread. The literature on rhubarb cultivation is scanty, so the illustrated bulletin, compiled by H. V. Taylor and E. E. Skillman, recently issued by the Ministry of Agriculture (No. 113. H.M. Stationery Office. 9d.) should prove a great asset to growers. The advice given relates generally to normal peacetime practice. Only a limited number of varieties are grown for commercial purposes, each is described in some detail and attention directed to the fact that all may be seen growing in the gardens of the Royal Horticultural Society at Wisley. The chief area of production is the West Riding of Yorkshire, though in Essex, Lancashire and Cheshire quite a considerable acreage is devoted to the crop. The high rain-

fall, acid soil and the capacity of the plant to withstand smoke pollution contribute to the success of the crop in the Leeds district, in fact the contaminated atmosphere is an asset for forcing purposes, as it induces premature leaf shedding and early dormancy. The cultivation of both forced and natural rhubarb are described at some length and a section devoted to grading, packing and marketing. As regards diseases, that termed 'crown rot' appears to cause most trouble. Eelworm infection is now thought to be largely responsible for this, though it is not yet clear whether there are not also other factors which contribute to this condition.

Plea for a Museum for Croydon

DR H. W. DICKINSON's presidential address this year to the Croydon Natural History and Science Society discussed the proposal for a museum for the district. Croydon is the largest borough in Great Britain without an adequate museum service, and he stated that the Society is now urging the proposal upon the local authority "as one of the particular objects to be carried into effect in the post-war municipal reconstruction scheme". If the museum materializes, he stressed the importance of a localized policy, and in this connexion suggested that a plan already exists in the form of the Society's Regional Survey of the district. Alluding to museum functions, he placed 'research' before 'visual education', but in view of the present-day urgent need for all forms of education, the smaller regional museums might usefully reverse this order. Dr Dickinson justifiably deprecated the use of old dwelling-houses for museum purposes, for these do not provide the offices and facilities required for the execution of a useful and progressive service. Referring to the reluctance of municipalities "to spend money on buildings even if they own valuable collections", he reminded the audience that the Nuffield Trust, and the Carnegie United Kingdom Trust, could be approached for financial help. Clearly, Dr Dickinson has closely studied Markham's report on "The Museums and Art Galleries of the British Isles" (1938), and all authorities undertaking the establishment or reorganization of regional museums in the future could profitably follow his example.

The Cinema

MR LINDGREN's pamphlet "The Cinema" (English Universities Press, Ltd. 4d. net) well maintains the standard set in this Handbook for Discussion Groups series, and should serve as a useful basis for discussion of various aspects of the cinema, including the Report of the Board of Trade Committee on Tendencies to Monopoly in the Cinematograph Film Industry, of which little has been heard since its publication. This particular aspect is indirectly touched by one of the subjects listed for discussion, but in the brief compass of nineteen pages Mr Lindgren contrives to supply a good deal of background and to indicate most of the broader issues involved, such as the possibilities of the cinema in scientific research, education, the recording of history, the promotion of international understanding and the field of public information. He touches succinctly on the general problems of the entertainment value of the cinema, its influence and the question of censorship, where in two brief paragraphs he brings out the essential weaknesses and dangers inherent in censorship, and incidentally supplies adequate justification for the attempt to stimulate further discussion.

of the whole problem. There is an eminently practical note in the whole pamphlet, and if a word of criticism is called for, it is that the bibliography, even within the limits set, might have been improved.

The Cooper Union Annual Report

THE report of the Director of the Cooper Union, of New York, for the year ending June 30, 1944, covering the eighty-fifth year of the Institution, indicates that, although in some respects the disturbance of education in the United States under the impact of war has been less profound than in Great Britain, the problems of demobilization and of re-training are being faced along similar lines. There is an interesting parallel between educational thought, as portrayed in this report, in the two countries. Stress is laid upon the necessity of finding a strong and socially satisfying ethical foundation for modern education, on the limitations of the scientific method, and on the importance of no longer confining instruction and discussion in the human and spiritual values to the level of higher education and the liberal arts. The humanities and the social sciences should be brought into the curriculum of the high school, vocational school, junior college, technical institute and engineering school. The Department of Humanities of the Union has been successfully experimenting since 1939 with the integration of social and humanistic studies with the curricula of the schools of engineering and art, and is now offering a sequence of studies which, taken as a whole, should give a perspective of the history of Western culture and an appreciation of their roles as citizens and as individuals.

The report recognizes that the professional world of engineering and art properly demands a breadth and depth of preparation and a sophistication which cannot be gained by conventional class-room routine. The Cooper Union has been able to keep the nucleus of the teaching staff of its School of Engineering reasonably close to normal in the war period, and resumption of full teaching loads after the War can therefore be undertaken with speed and efficiency and with only minor additions to the staff. Policies to be followed with regard to the re-training of the demobilized and their integration into academic and social life are indicated, and a sub-committee of the Engineering Faculty has set itself the task of determining those qualities and attributes which should characterize the products of the four engineering curricula. Reference is also made to the work of the Student Health Service in educating the student in the use of the facilities already existing in the surrounding community, and of the Division of Social Philosophy, which completed its first decade during the year, in the field of adult education.

Museums and Adult Education

AN editorial article in the *Australian Museum Magazine* (June-August, 1944) directs attention to the contribution which museums have already made towards adult education. At the same time, it points out that there still remains the necessity for far greater extensions of the museums' services in this direction. It is suggested, for example, that museums should be available to the public out of ordinary working hours, that there should be better accommodation for study, and that there should be an increase of suitably qualified staff to guide and assist students.

Society of Public Analysts and Other Analytical Chemists

THE annual general meeting of the Society of Public Analysts and Other Analytical Chemists, held on March 9, marked the seventieth anniversary of the Society. In the past year the membership of the Society increased by 117 to 1,197, and the circulation of the Society's journal, the *Analyst*, in spite of paper restriction, increased. In pursuance of the policy decided upon a year ago, the Society recently formed, within the framework of its constitution, two Groups concerned with particular branches of analysis, namely, the Microchemistry Group (chairman, Prof. H. V. A. Briscoe, hon. secretary, Mr R. Belcher, present membership, 143) and the Physical Methods Group (chairman, Mr R. C. Churnside, hon. secretary, Dr F. Wokes, present membership, 115). These Groups will hold meetings from time to time in London and elsewhere. The proceedings terminated with the presidential address of the retiring president, Mr S. Ernest Melling, who, after reviewing some of the outstanding events of the past year in the Society's affairs, made some observations on the subject of water and water supplies. Dr G. W. Monner-Williams was elected president for the present year.

Science Masters' Association's Annual Meeting

THE annual meeting of the Science Masters' Association will be held during April 9-11 at the City of London School. The president, Mr C. L. Bryant, will speak on "The Impact of Science on Common Thought". The proceedings will include lectures by Dr J. McG. Bruckshaw on "Physics and Economic Geology", Mr C. Bibby on "Health Education through School Biology", "Penicillin", by Sir Alexander Fleming, "Scope and Limitations of the Science Teaching Film", by Mr A. Elton (at the Ministry of Information Theatre), "The Electron Microscope", by Mr F. W. Cuckow, "Chemistry of Plastics", by Mr R. Mantland, and a discussion on "The Role of Science in the Future Educational System". There will also be the usual exhibitions. The third lecture on the Science and Citizenship Foundation will be delivered by Mr J. G. Crowther, who will speak on "The Social Relations of Science", this lecture is open to the public, and tickets for visitors can be obtained from Mr W. Ashhurst, Epsom College, Surrey.

Announcements

THE Bristol Aeroplane Company has given £60,000 to the University of Bristol for the establishment of a Sir George White chair of aeronautical engineering, in memory of the founder of the Company.

THE Biochemical Society and the Nutrition Society have arranged a joint whole-day conference on "The Vitamin B-Complex", to be held on April 28, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1. Details of the programme will be published later.

PROF. JAMES MACKINTOSH, dean of the London School of Hygiene and Tropical Medicine, is visiting Sweden to lecture for the British Council on aspects of social medicine and health education in Britain. He will probably also visit Finland. Prof. Mackintosh hopes to obtain in Sweden information for inclusion in a report on housing which he is preparing for the British Government.

Presentation of Scientific Data

WORKERS in certain branches of science have to carry in their heads many numerical results and constants, and to read and abstract a vast literature. This becomes even more arduous for those on the borderline between the exact and the descriptive sciences. The difficulties are greatly increased by the less rigorous presentation of borderline results, and by the less stringent editing of journals dealing with a variety of subjects. In chemistry and in physics the symbols and quantities are standardized, but in the applications little regard may be paid to recognized usages. A report drawn up by the Chemical, Faraday and Physical Societies in 1937 listed symbols for thermodynamical and physico-chemical quantities. These were accepted by the Royal Society in 1939. There are, however, many quantities not included in the list. For these, reference to the International Critical Tables or to the Smithsonian Tables is helpful. One major difficulty arises from the fact that the Greek letters and diverse founts of type are lacking on ordinary typewriting machines.

For numerical results it is suggested that, if possible, indices should be avoided, and when used they should refer to the basic unit. Though one may write 17 cm, it is preferable to avoid 17×10^{-4} cm and to write 17×10^{-6} m, or better, 17 μ . This would be an aid to memory.

It would be a convenient convention if droplet sizes were given as diameters, rendering comparable, for example, the length of a bacillus and the diameter of a coccus with spray droplets. But at present those who measure droplets give diameters and those who carry out mathematical investigations give radii.

It is very confusing when quantities in the same analysis are given in different units. Workers in nutrition are offenders in this. For lack of better, they have to give certain quantities as I.U. (international units), but there is no defence for giving in consecutive lines of a table a vitamin as 19 μ gm/gm and iron as 1.9 mgm/100 gm, whereas in fact the two quantities are identical. It would appear simpler to give both results in parts per million. Why do they darken understanding by reporting such quantities as per ounce of, say, bread? Surely micrograms are meaningless to workers in ounces, but anyone can understand percentages, parts per thousand and per million. Why write 10^{-8} oz? It sounds ridiculously small and indefinite, but is actually slightly less than 0.3 μ gm. One may be surprised at detecting a substance "even in a concentration of 1×10^{-10} g per μ^3 ", but the feat is more credible when bluntly put as 0.1 gm per litre.

It is somewhat of a shock to find depths of corrosion pits given in thousandths of an inch (mils) and the thickness of the overlying paint in microns, but to give the application of paint in square feet per gallon (Imperial or U.S.A.) is convenient and logical, with just this drawback, that it renders the determination of film thickness—simple in the metric system—quite complicated. Also one wonders why anyone should be allowed to report permeability "as milligrams of water per day per square centimetre of film area per mil of film thickness", or a liquid for

destroying insects in cubic centimetres per 37 cubic feet of air, instead of using the factor 2360 to convert to the same unit of volume and reporting as parts in 87,000, or per 100,000. All the cases instanced have been met with recently. Furthermore, why do physiologists speak of the tension of oxygen, when they mean the pressure—and why, when a paper went to the Chemical Society giving the boiling point of a pure liquid as so many degrees at so many millibars pressure, was it sent back for conversion to millimetres of mercury, though the Meteorological Office publishes the atmospheric pressure in millibars? Could we not be a little more consistent—and spare our memories unnecessary figures? Could we not in technical reports use the metric system universally and translate such quantities as have workshop application into the British system—where necessary? At present there is often a medley of both systems with a vast waste of time in conversion from one unit to another. In measuring light we have even got to the mile-candle. Before autumn one may find candles per acre. After the War, Britain will be poor, so why should we handicap our scientific and technical development by carrying an antiquated system of measurement into new fields? But for those who have to convert, the British Standards Institution Publication 350 (1944) Conversion Factors and Tables is useful.

Sublimation in a Wilson Chamber

As a result of some experiments on the deposition of water vapour at low temperatures, it was found that the liquid phase can frequently exist much further below the freezing-point than was expected. For example, droplets of super-cooled water can be obtained at -50°C without difficulty. It appeared also that the number of nuclei in atmospheric air on which water vapour could form ice crystals without the previous formation of droplets was small, and they appear to be active only below about -40°C . Arrangements were therefore made to repeat Prof. C. T. R. Wilson's classical experiments below the freezing-point, both in thoroughly clean air and in ordinary atmospheric air. The following results were obtained.

Air thoroughly cleaned by repeated expansions

(1) Provided that the lowest temperature after expansion (that is, the temperature when expansion is finished and condensation just starts) does not fall below -35.0°C , only liquid droplets are formed, however big is the expansion ratio.

(2) If the lowest temperature after expansion falls to -35.1°C ($\pm 0.1^\circ$) a few ice crystals are formed among a much larger number of droplets. As the minimum temperature falls further below -35°C , more ice crystals and fewer droplets appear, so that at lower temperatures a fog of ice particles is formed. Whether or not the solid phase appears depends only on the minimum temperature and not at all on the supersaturation.

(3) Provided that the lowest temperature after expansion falls below -35.0°C , ice crystals are formed although the expansion is below the normal critical ratio.

(4) When the lowest temperature after expansion falls below about -80°C , the number of particles formed decreases and a few of them change in appearance from transparent ice crystals to much larger grains of soft hail. At about -100°C only a few such grains fall down after expansion. Below about -120°C no particles are formed. The result does not depend on the expansion ratio, provided it is big enough to make the products visible.

(5) If the air be ionized by X-rays before the expansion, the density of the ice cloud formed is very greatly increased, but the limiting temperatures are not altered.

Ordinary atmospheric air (1) The limiting temperature of -35.0°C found for clean air becomes -27°C , and varies by $\pm 0.5^{\circ}\text{C}$ from one experiment to another. With air artificially contaminated with tobacco smoke the limiting temperature for the appearance of ice was as high as -23°C .

(2) At the lower temperatures (-80° to -120°C) the same decrease in the number of particles and the same changes in their appearance occur as in thoroughly clean air.

During the course of experiments, the expansion chamber was surrounded by a cooling bath of different temperatures, all below freezing point. A certain test to indicate the presence of the minutest amount of ice was to have supercooled water in the bottom of the expansion chamber. If any ice appeared in the chamber, it could not escape detection. It could not melt because all the surroundings were below freezing point. Within a few seconds, any ice particles which may be formed would seed the super-cooled water either by falling to the bottom or by contact with the film of super-cooled water coating the walls of the chamber. Then the water would freeze.

Some preliminary investigation of the properties of super-cooled water made it possible to use this indicator for initial temperatures of the chamber between 0°C and -10°C . Samples of a few cubic centimetres of water which can be easily supercooled were prepared by distillation (without boiling) and then boiling the sample for a few hours. Each sample has its own 'freezing point' which it keeps within 0.1°C for, at least, a few months. The pressure, up to 100 atmospheres, does not affect the 'freezing point', but crystalline dust is not more active in this respect than amorphous dust. For initial temperatures below -10°C a long chamber was used. In such cases the ice particles which are formed high in the chamber grow sufficiently when falling to be observed in the beam of an arc lamp illuminating the bottom of the chamber.

It appears that ice particles formed in thoroughly clean air are formed by sublimation, and that sublimation phenomena due to adiabatic cooling differ essentially from phenomena of condensation since (a) the formation of ice particles seems to depend only on the minimum temperature reached after expansion, (b) even in thoroughly clean air they are formed at supersaturations which are far smaller than those necessary to form water droplets. These results would seem to have interesting applications to the formation of clouds in the higher atmosphere.

Explanation of the Joshi Effect

THE interesting experiments of Joshi and co-workers, on what they call the new light effect, relate to the decrease of current flowing in the high-voltage exciting circuit of a Siemen's ozonizer, when radiations fall on the chlorine gas contained within the ozonizer. Alternating voltages of the order of 10 kV. are applied between the inside and outside walls of the ozonizer and the current is measured, its order of magnitude being about 50 microamperes. The experimental arrangement and the description of the effect are given in recent papers by Deo¹ and Joshi².

An explanation of this effect seems to be possible from the quantum-mechanical dispersion formula of Kramers, namely

$$n^2 - 1 = 8\pi B \sum_{l,l'} \frac{\nu(l,l) |p_0^E(l,l)|^2}{h[\nu(l,l)^2 - \nu_0^2]} e^{-W_0/kT},$$

where $B = \frac{N}{\sum_l e^{-W_0/kT}}$, n is the refractive index of

the gas for the incident light, and ν_0 is the frequency of the atom or molecule corresponding to a transition from an energy-level $E(l)$ of quantum number l to the level $E(l')$ of quantum number l'

$$\nu = \frac{E(l') - E(l)}{h}$$

ν is negative if transition takes place from an excited level to a normal level. p_0^E are the unperturbed matrix elements of the components of the electric vector E of the primary beam.

The formula shows that in an excited gas, the refractive index should be less than that for the normal unexcited gas, due to the negative terms in the formula for the excited states. This expectation was experimentally established by Ladenburgh³ in neon. The equation applies to our case if we put ($n^2 = k$) the dielectric constant and ν_0 is the frequency of the electrical circuit, say, 50 cycles/sec. Hence when radiations fall on the chlorine gas, exciting it to higher vibrational and electronic states, the dielectric constant decreases and so does the dielectric current in the electrical circuit, which is essentially a condenser circuit, the plates of the condenser being the two electrodes of the ozonizer.

That our interpretation is not far from truth can be seen from the following considerations.

1. As the current is only of the order of 50 microamperes, for voltages of the order of 10 kV, it shows that it is mostly a dielectric current and not the ordinary ohmic conduction current. For a discharge current the magnitude would be of the order of one milliampere⁴. As a matter of fact, Joshi says in one of his papers that when experimental conditions were such as to get a faint glow in the gas, the light effect decreased. This was due to the conduction part of the current having been increased, with the consequent decrease of the change of dielectric current with radiation, as percentage of the total current.

2. The effect is a maximum in white and violet light compared to that for lower frequencies, whereas chlorine has its maximum absorption in the former. This corresponds to increase of magnitude and the number of the negative dispersion terms. Both these effects make the relative change of current bigger numerically.

3. The maximum of the effect occurs, on the whole, in regions of lower voltages, because the lower the

voltage the more is the current of dielectric or displacement nature

4 The maximum of the effect occurs at some range of pressures, neither too high (atmospheric) nor too low. At higher pressures, though the number of molecules is higher, the life and hence the relative number of the excited states will be lower on account of greater loss by collisions. Again, with decrease of pressure, the magnitude of the discharge current would increase, making $\Delta\epsilon/\epsilon$ numerically small. A compromise of all these factors leads to an optimum pressure (of the order of 50 cm. mercury) for particular experimental conditions.

An indirect experimental confirmation of our interpretation is the fact that the dielectric constant of ionized gases is less than unity. An excited molecule and an ionized molecule are different stages in the same direction. There may be other minor points associated with the effect, having different causes, for example, the influence of walls of the ozonizer on $\Delta\epsilon/\epsilon$, etc., but for the main fact of decrease of current with irradiation the effect of negative dispersion terms seems to be the right cause.

A possible weakness in our interpretation is that the intensity of the excited states is usually regarded as small as compared to the normal state.

Fuller details will be published later on

'Anomalous' Behaviour of the F_2 Region of the Ionosphere

It has been known for some years that the seasonal and diurnal variations, and the geographical distribution of the maximum electron density N in the F_2 layer, the main observable region of the ionosphere, are anomalous in that they do not conform to the simple Chapman theory of ionization production, according to which N should be proportional to $\cos \chi^{1/2}$, where χ is the zenith distance of the sun. For example, in temperate and high latitudes in the northern hemisphere, the noon values of N show a minimum in mid-summer and a maximum in mid-winter, a variation which is exactly out of phase with theory, while in the southern hemisphere in temperate latitudes noon N exhibits maxima near the equinoxes and minima in mid-summer and mid-winter.

Two theories usually are jointly invoked to explain these and other similar anomalies. According to the first, the low values of N in mid-summer are due to a great expansion of the upper atmosphere by solar heating. On the Chapman theory, N is proportional to $T^{-1/2}$, so that such heating, if great enough, might explain the lowering of noon

N in mid-summer. This view appears to be supported by the fact that h' (max.), the height at which N is found, is some 150 km. greater in summer than in winter. The second theory explains the different type of variation in the northern and southern hemisphere as due to a superposed annual variation of ionization, of unknown origin, which has a maximum throughout the world in December-January and a minimum in June-July. Simple calculation shows that the expansion theory demands a summer value for T of the order ten times greater than the winter value, which is highly improbable on any reasonable theory of radiative equilibrium in the ionosphere, so that it seems desirable to explore other possible explanations of F_2 region anomalies. Evidence in support of an alternative theory is supplied by the data shown in the accompanying graph, which compares the monthly mean minimum equivalent heights h' for north temperate, south temperate and equatorial locations for the period 1937-41. The locations are, respectively, Washington, D.C., the mean of Watheroo and Canberra (Australia) and Huancayo (Peru). The data used were taken from that published regularly in *Terrestrial Magnetism and Atmospheric Electricity* during these years, together with the unpublished records taken at the Commonwealth Solar Observatory, Canberra. The Huancayo graph is drawn as a dotted line when the sun is to the south.

It will be seen from the graphs that the height variations in the northern and southern hemisphere are out of phase, showing a true seasonal variation, with maxima in mid-summer, as the 'heating' theory would predict. On the other hand, it is seen that h' at Huancayo does not show maxima when the sun is overhead (that is, in February and October), in disagreement with this theory. Inspection shows, however, that the Huancayo graph parallels that of Washington when the sun is north of Huancayo and parallels that for Australia when it is in the south. (The more complex graphs for N at the same stations, which are not reproduced here, show the same phenomenon.) This behaviour, which is similar to that of the diurnal variation of the magnetic declination at Huancayo, suggests strongly that the variations of h' and N are controlled, as are the magnetic variations, by large-scale tidal movements in the upper air.

Evidence for the existence of such a tide at these levels is presented in a separate communication. The

different seasonal behaviour of N in the two hemispheres is believed to be due to a difference in the seasonal variation of the phase of the tides in the two hemispheres

Magnetic Properties of some Paramagnetic Crystals at Low Temperatures

MEASUREMENTS have been made on the principal magnetic susceptibilities of single crystals of a large number of paramagnetic salts of the iron group, from room temperature down to about 80° K. A detailed discussion of the results on the basis of the crystalline field theory will shortly be published elsewhere. According to this theory, the deviations from the simple behaviour to be expected of the free ions are attributed to the Stark splitting of the energy-levels of the paramagnetic ion under the influence of the strong and generally asymmetric electric field that occurs in the neighbourhood of the paramagnetic ions in these crystals, due to the negatively charged atoms that surround these ions. The following are some of the main results obtained.

In manganous and ferric salts in which the paramagnetic ion is in the S -state, the anisotropies are negligibly small, and the temperature variation of the susceptibility almost exactly follows the Curie law $\chi = C/T$.

In chromic salts also this is so, even though the Cr^{+++} ion is not in the S -state. This is due to the fact that the lowest level in the Stark pattern of Cr^{+++} is a singlet, and it is widely separated from the upper levels, the singlet level, however, has a $(2s + 1)$ -fold spin-degeneracy.

The nickel salts are very similar to the chromic salts in their magnetic behaviour, except that the spin-orbit coupling in Ni^{++} is much greater than in Cr^{+++} , and this conduces to a much larger deviation from the S -state behaviour than in Cr^{+++} , in other words, it leads to an appreciable magnetic anisotropy and deviation from the Curie law. These deviations are utilized to calculate the crystal field constants, and it is found that not only the cubic part of the field which is predominant, but even the rhombic part which is small, is nearly the same in most of the nickel salts, and they are practically independent of temperature.

In both Co^{++} and Fe^{++} salts, owing to the ground-level being a triplet, the magnetic properties are more sensitive to the rhombic part of the field than in the nickel salts. An estimate has been made of the rhombic part of the field.

The copper salts, as judged by their magnetic properties, fall into three distinct classes. In the first class all the principal susceptibilities follow the Curie law, but with different Curie constants, that is, the effective moments are different for different directions, but all of them are practically independent of temperature. To this class belong the Tutton salts. In the second class the principal moments are nearly the same as before, but they all decrease with the lowering of temperature, slowly at first and rapidly at later stages. The double chloride of copper and ammonium is a typical example of this class. To the third class belongs cupric acetate monohydrate,

in which the principal moments are all very low even at room temperature and decrease rapidly as the temperature is lowered. The three classes correspond to the non-cubic part of the crystalline field, being very different, lowest in the first class and highest in the third.

The influence of covalent binding on the strength of the electric field, and ultimately on the breaking of the Russell-Saunders coupling not only between the spin and orbital moments, but also between the spins of the different electrons of the ion, and its effect on the magnetic properties of the ion, have been discussed.

Though in the majority of the crystals the magnetic axes do not change their directions in the range of temperatures studied, the change is appreciable in some crystals, the largest change observed being 7°.

There is an axis of magnetic symmetry in nickel and ferrous salts, even though the crystal structure does not lead to it.

My thanks are due to Prof K S Krishnan for his interest in this work, and to the Indian Association for the Cultivation of Science, Calcutta, for facilities for carrying out the experiments.

Theory of Viscosity of Concentrated Suspensions

FOR infinitely diluted suspensions of rigid spheres, Einstein¹ derived on a rigorously theoretical basis the formula

$$\eta = \eta_0 (1 + kc), \quad (1)$$

where η is the viscosity of the suspension, η_0 is the viscosity of the pure solvent, c is the concentration by volume and $k = 2.5$ is a constant. It has been shown that (1) is also valid for non-spherical particles, the factor k being a function of their shape, rigidity and Brownian movement. For elongated rigid particles, $k > 2.5$.

If it is assumed that the suspension behaves hydrodynamically with respect to an additional particle as a homogeneous medium, it is possible to derive a theoretical viscosity formula for higher concentrations. Let us add a particle of a volume dV to a suspension of viscosity η , containing already a volume V of similar particles in a volume A of the pure liquid. Then the increase of the viscosity should be

$$\eta + d\eta = \eta \left(1 + k \frac{dV}{A + V} \right), \quad (2)$$

or after a slight rearrangement

$$\frac{d\eta}{\eta} = k \frac{dV}{A + V}, \quad (3)$$

which can be easily integrated, giving

$$\eta = \eta_0 (1 + V/A)^k = \eta_0 (1 - c)^{-k} \quad (4)$$

If $c = 0$, $\eta = \eta_0$, so that the integration constant η_0 is the viscosity of the pure liquid.

The assumption of hydrodynamical homogeneity of the suspension holds only if the particles are sufficiently far apart, so that their mutual interactions other than a general increase of viscosity are neglig-

ible However, under the shearing motion of the liquid the particles move relative to each other and collisions occur These do not resemble collisions in a gas, the particles rolling round each other, until they reach such positions that a disengagement through further shear takes place

It can be shown for suspensions of rigid spheres that each sphere is in collision for an average fraction of time proportional to the concentration c During this time the colliding pair increases the viscosity more than a separated pair, due to a combination of several effects The most important effect is caused by a certain volume of liquid being immobilized around the point of contact This volume is proportional to the volume of the spheres The total immobilized volume qVc , where q is a proportionality constant, should be thus subtracted from A and added to V in equation (4) Whence

$$\eta = \eta_0 [1 + (V + qVc)/(A - qVc)]^k = \eta_0 (1 - c - qc^2)^{-k} \quad (5)$$

The constant q was calculated by an approximate method to be not far from unity for rigid spheres, and it is expected to be much less, if the spheres are soft, as there will be less liquid immobilized around the point of contact The shape factor k should also change slightly with concentration, as two colliding spheres behave as one non-spherical particle, but this effect is negligible compared with the effect of the immobilized liquid

As there are no accurate viscosity data available for concentrated suspensions of rigid spheres, measurements of Erich, Bunzl and Margaretha² extending only up to about 20 per cent, measurements of suspensions of glass spheres were made to test the formula (5) The glass spheres of 0.013 cm. diameter

were kindly loaned by Dr F Erich, being the same as those in his investigations. The spheres were suspended in a saturated solution of zinc iodide in water and glycerine which has the same density as glass and a high viscosity of 80 centipoises at 20° C., this made corrections for inertia effects of the spheres unnecessary

Measurements were made in two Ostwald viscometers, having diameters of the capillary 0.23 cm and 0.38 cm, and in a Couette apparatus with diameter of the inside cylinder 1.264 cm, of the outside cylinder 3.6 cm The uncorrected measurements from different viscometers were in disagreement with each other, but after being corrected for the wall effects they agreed surprisingly well, as can be seen from the accompanying graph, where the corrected results from different instruments are plotted against concentration The full curve represents formula (5) with values of $k = 2.5$ and $q = 1.16$, which are the values fitting best the measurements The agreement of the measurements with the formula (5) is well within the experimental error up to a concentration of 37 per cent

Above this concentration, suspensions subjected to shear are no longer isotropic and exhibit different viscosities in different directions, the rate of shear ceases to be proportional to the shearing stress and depends on the previous history of shears

I wish to express my thanks to Dr F Erich for the loan of the spheres Detailed results will be reported elsewhere

Fluidity and Molecular Structure

It was pointed out by Porter¹ that, for mercury and water, the logarithm of the viscosity is a linear function of the logarithm of the vapour pressure I propose a modified relationship introducing the critical pressure p_c , namely,

$$\log \phi = a \log p/p_c + d,$$

where ϕ is the fluidity of a liquid at the vapour pressure p , a and d are constants

Putting $p = p_c$, then $d = \log \phi_c$, and we can write

$$\log \phi/\phi_c = a \log p/p_c \text{ or } \phi/\phi_c = (p/p_c)^a \quad (1)$$

It has been found that, with the exception of associated substances, and apparently a small number of liquids possessing highly symmetrical molecules, a does not differ greatly from the mean value of 0.24 for all pure compounds examined Equation (1) expresses an interesting extension of the theory of corresponding states, for it implies that, at the same reduced pressure, non-associated liquids have nearly the same reduced fluidities Furthermore, as a rough approximation, such liquids possess the same value of $d = \log \phi_c$, and so the fluidity or viscosity of a substance depends primarily on its 'distance' from the critical state

In the simple Porter equation, $\log \phi = a \log p + b$, b is the value of $\log \phi$ at some arbitrary unit pressure, for example, expressing p in standard atmosphere

RELATIVE VISCOSITY OF SUSPENSIONS OF GLASS SPHERES AS A FUNCTION OF CONCENTRATION BY VOLUME

Ostwald viscometer measurements, capillary diameter 0.23 cm, ●, capillary diameter 0.38 cm, ○, Couette viscometer measurements, □ Theoretical curve calculated from the formula (5) with $k = 2.5$, $q = 1.16$, full line

units, b becomes $\log \varphi_B$, the logarithm of the fluidity at the boiling point under 760 mm of mercury pressure

For substances examined having a approximately 0.24, it has been found that the function $M \log \varphi_B$, where M is the molecular weight, can be evaluated from a list of atomic and structural constants, and the fluidity of a given non-associated liquid at its boiling point be calculated with an average error of 3 per cent

Work on these lines is now in progress together with an examination of the above relationships as applied to liquid solutions. Full details will be published as soon as possible

Effect of Electrically Induced Convulsions on the Sugar Tolerance of Psychotic Patients

IN this Hospital, investigations are being made on the sugar tolerance curves of a number of psychotic patients. Abnormal curves in such patients have been found by workers in the past^{1,2}

As progress is comparatively rapid during electric convulsion therapy, it was felt that possible changes in these curves during treatment might be present and this was in fact found to be so. Patients suffering from depressive and manic depressive insanity show the greatest abnormality in their sugar tolerance and also the greatest change in this during treatment. The typical curve before treatment is shown in the accompanying graph. The fasting level is normal or slightly raised, there is a rapid rise to heights well above physiological limits followed by a sharp descent, but not reaching the original level in two hours.

After two to six convulsions, although the mental condition improves, the curves show increasing

SUGAR TOLERANCE CURVE
Full line, patients broken line, average normal

abnormality. Thus, in most cases the fasting level is raised and the maximum reached in half or one hour is in the region of 0.4 gm per cent. Gradually, after the mental condition has been normal for many weeks, the curves become normal too.

In all cases of depression the first effects of electric convulsion therapy on the sugar-tolerance curve is to raise both the fasting level and the maximum.

This profound physiological disturbance described above is of great significance since it shows, at least for some mental disorders, a relationship between metabolism and the so-called functional disorders.

This investigation is being continued.

Oestrogenic Substances showing Anti-tumour Action

CONTRARY to the general impression (due to publications attributing carcinogenic properties to oestrogens when administered to both sexes of different animals, also the oestrogenic activity, although notably weak, of many carcinogens), I have during my researches^{1,2} on oestrogens come to believe that these compounds are not carcinogenic, and that they will most probably show at least some curative influence in the case of tumour diseases. I submitted a detailed report on "Oestrogens as Anti-tumour Compounds" to the Ministry of Public Health in Egypt on May 30, 1944. An account of the influence of synthetic oestrogens upon advanced malignant disease was recently published³.

Owing to the remarkably prolonged action of α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene^{4,5} when given orally, and its remarkably low toxicity, if any⁶, it was proposed to use this substance in the treatment of ovarian tumours and cancer of breast. The following describes its influence in two cases of cancer.

Case 1 A patient fifty-seven years old was operated on for breast cancer, the right mammary gland being removed. Seventeen months later recurrence with metastases in the liver was noted. Within the next eight weeks the patient became much worse, became dumb, the faeces became colourless apparently indicating biliary obstruction, and oedema developed in both legs and in the right arm. On July 3, 1943, a 100-mgm cachet of α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene was given to the patient, and on the following three days, a 250-mgm cachet was given daily. The oedema completely disappeared within five days from the beginning of the treatment, the faeces resumed the normal colour and the patient spoke once. The patient, however, died on July 10, 1943.

Case 2 A patient aged forty-five suffering from sarcoma ovarialis of a comparatively large size had the abdomen opened in the King's Hospital, Cairo on July 31, 1943, and the tumour being inoperable was left untouched. The tumour continued to increase in size, filling the abdomen and pressing against the different abdominal organs. Treatment with α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene began on August 23, 1944, the oestrogen being administered

orally (6-8 gm. monthly, in 200-mgm. cachets, once, twice or thrice daily with intermittent intervals of 2-3 days every 3-5 days). A considerable improvement took place. Dr. Hamed Mohamed El Dewany, the private physician of this patient, states: "the patient suffered from sarcoma ovarialis. Surgeons and radiotherapists, who were consulted, considered the case hopeless. With the administration of α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene proposed by Dr. Wadie Tadros, the tumour softened and decreased in size, and the patient was relieved from pain". The tumour, although at a slower rate, is at present continually regressing.

It is remarkable to note the drop of temperature almost to normal within 3-4 days after the administration of α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene to cancer patients with temperature above normal. When tested *in vitro*, however, it was reported⁷ that it had no anti-bacterial action.

Robson and Ansari⁸ noted that the fate of this substance was, in some respects, very different from that of the oestrogens so far studied. Unlike the natural oestrogens, which are rapidly inactivated (chiefly by the liver), and stilboestrol, which is rapidly eliminated from the body after absorption, it is stored in the body tissues to an appreciable extent and is eliminated comparatively slowly.

Although the administration of oestrogens in attempting to treat malignant diseases gave in many cases beneficial effects, it is to be noted that in dealing with the problem of these diseases, many factors, apparently interrelated, have to be taken into consideration. Among these may be mentioned the anaemia prior to or after the development of the malignant disease, secondary infections, degree of malignancy and toxæmia due to necrosis of tumour tissues. Moreover, it seems likely that controlled application of both radio- and oestrogenic-therapy may sometimes be desirable rather than the administration of high overdosage of the oestrogen alone, provided that other factors such as anaemia, toxæmia, etc., referred to above, can be dealt with. Prophylactic implantation of oestrogens following surgical and radium castration has been reported⁹.

The application of α -di-(*p*-ethoxyphenyl)- β -phenylbromoethylene in an attempt to treat different types of malignant diseases is in progress in collaboration with different medical investigators, and results will be published when sufficient data are available. In the meantime, I am continuing investigations on the synthesis of more highly active oestrogenic compounds with greater anti-tumour effect.

Foot Rot (*Phoma* sp.) of Flax

Foot rot disease of flax caused by a species of *Phoma* was first recorded in Ireland by Pethybridge *et al.*¹ in 1921. Since then it has been noted to occur consistently in the Northern Ireland crop although the responsible species of the parasite still awaits identification. A review of the literature indicates that *Phoma* has been reported as attacking the flax crop on the Continent of Europe since the 1890's, and, more recently, in Australia², the causal organism being variously referred to as *P. exigua*, *P. herbarum* and *P. linicola*.

Foot rot first becomes readily noticeable during mid-season when odd plants here and there in the crop show a wilted appearance. On pulling affected plants, pycnidia of *Phoma* will normally be found to occur in profusion along the basal portions of the stems (see photo.). The plants die prematurely and turn brown while the remainder of the crop is still green. Although foot rot is the phase usually encountered, the fungus can attack and kill the plants in the seedling stages (see photo.); the nature of the attack and the symptoms produced are largely determined by seasonal growth conditions.

The disease may be found if searched for in almost any season, but, until 1944, it was seldom found attacking more than a few straws in any crop, and it was for this reason that Pethybridge and Lafferty included it in the group of less important flax straw diseases referred to collectively as causing 'dead stalks' in the crop. That the disease may be of a serious nature and of epidemic importance was revealed in 1944 when some crops in Northern Ireland, Scotland and Wales were seriously affected; this epidemic outbreak was quite unexpected and, until then, no such cases had been recorded.

The pathogenicity of *Phoma* towards flax is well known, and has been confirmed by our experiments. Until now, however, it has been generally assumed that the parasite is normally soil-borne and that infection is most likely to occur through the medium of the soil. This may be so, but evidence accumulated during the past few years shows that the parasite may be seed-borne and indicates that the seed may be a more effective means for transmission than the soil. Seed produced in the more northerly and westerly parts of the United Kingdom is much more likely to be contaminated with the parasite than that produced in the south and east. This is due, no doubt, to climatic conditions and to the greater difficulty of harvesting non-weathered crops in the north and west. There is also a tendency towards a building up of seed contamination when seed is successively saved from crops grown in areas liable to favour the incidence of the disease and when a succession of poor seasons is experienced. It has been found possible to use the Ulster method³ for determining the extent of seed contamination and this has proved most useful in the separation of clean from contaminated seed.

The fact that the parasite may be seed-borne raises the question of the efficacy of seed disinfection in clearing it from a seed sample. Using the same technique as that devised for *Colletotrichum linicola* and *Polyspora lini*⁴, we have carried out a large number of laboratory tests with the following results. 'Nomersan' (10 per cent tetra-methyl-thiuram disulphide), which has proved effective for the control of *C. linicola* and *P. lini*^{5,6}, did not give very satisfactory results in the case of *Phoma*; repeated trials indicate it to be about 50 per cent effective when

LEFT, FLAX STEM ($\times 6$) SHOWING PYCNIDIA OF *Phoma* SP.;
RIGHT, FLAX SEEDLINGS ATTACKED BY *Phoma* SP.

used at the rate of 12 oz. per cwt. of seed. The short wet method of seed treatment using an 8 per cent solution of 'Ceresan U.564' at 0.9 gall. per cwt., although more effective than treatment with 'Nomersan', still did not provide adequate control. Further trials have been made using 'Arasan' (50 per cent tetra-methyl-thiuram disulphide), 'New Improved Ceresan' (5 per cent ethyl-mercury-phosphate), 'Fermate' (ferric dimethyldithiocarbamate) and 'Spergon' (98 per cent tetrachloro-*para*-benzoquinone). Of these materials promising results have been given by 'New Improved Ceresan' and 'Arasan'. Using 'New Improved Ceresan' at the rates of 12 oz. and 9 oz. per cwt. of seed, the contamination of a seed sample was reduced from 32.6 to 2.0 per cent and 5.5 per cent respectively. 'Arasan' used at the same rates reduced contamination to 10.8 per cent and 14.5 per cent. In the case of 'Arasan' it is of interest to note that the duration of the test had to be extended from seven to twelve days as this disinfectant exerts an inhibiting effect upon the fungus. No such effect was noted in the case of 'New Improved Ceresan' which appears to be more directly toxic. Whereas 'New Improved Ceresan' showed generally powerful fungicidal and bactericidal activity, the same selectivity was noted in the case of 'Arasan' as with other disinfectants with tetra-methyl-thiuram disulphide as the active constituent; in the case of bacteria and some fungi these materials have little or no effect.

Although it has not yet been possible to arrange for field trials with these materials, the high degree of correlation obtained between the results from laboratory and field trials in the case of *C. linicola* and *P. lini*⁷ suggest that results obtained in the laboratory should also be closely applicable in the field in the case of *Phoma*. It is proposed to adopt the use of both 'Arasan' and 'New Improved Ceresan' on a commercial scale during 1945. Of all the disinfectants tested for flax, 'New Improved Ceresan' offers the greatest promise for seed-borne diseases generally, its only drawback being its poisonous nature when compared with 'Arasan' and 'Nomersan'.

Tests made with samples of seed treated with 'Arasan' or 'New Improved Ceresan' at the rate of 12 oz. per cwt. have shown that such treatment has no effect upon germination. No adverse effects upon germination have been observed after treated seed

has been stored for eight weeks either in small packets in the laboratory or in hundredweight lots subject to ordinary storage conditions. In all cases the moisture content of the seed used was below 10 per cent.

A Method of Estimating the Activity of Spermatozoa

IN view of the absence of any satisfactory method for the quantitative estimation of the motility of spermatozoa, it is believed that the following method, evolved in relation to work on human semen, may prove of interest.

The semen is diluted with warm phosphate-glucose solution¹ (one in twenty gives a satisfactory dilution for semen containing 70–200 million sperm per c.c.). The dilution is thoroughly mixed by bubbling air through it with a pipette. One drop of fluid is placed on each of two Thoma counting slides. Over one drop is inverted a small straight-sided glass capsule lined with filter paper moistened with 2 per cent osmic acid. The osmic vapour permanently immobilizes all the sperm in about ten seconds. The capsule is removed, and cover slips are placed on both drops, taking the usual precautions to avoid running over. If the capsule is kept upside down on a glass plate, one drop of osmic acid will last about six hours.

The slides are put aside to allow the sperm to settle, that with the motile sperm being placed on a warmed microscope stage. After five minutes this slide is examined and a count made of the immobile, and of the feebly moving but non-progressive sperm in 160 small squares. The two figures thus obtained may be stated as x and y respectively. The actively moving sperm are ignored. A count is then made on the osmicated slide of all the sperm in 160 small squares, giving a figure z . Subtraction of $x + y$ from z gives the number of active sperm in the suspension corresponding to a total number of sperm z , and a volume of fluid contained in 160 small squares.

Sperm which have been cold for an hour or longer do not all become active immediately when mixed with warm diluting fluid, and maximum motility may not be reached until the dilution has been kept at 37° C. for an hour.

When repeated estimations of motility are required during the course of an experiment, it is essential to take two drops for comparison each time, as clumping or disintegration may cause a progressive reduction in the total number of sperm in the suspension.

This work has been assisted by a research grant from the Family Planning Association.

MEAT IN GREAT BRITAIN

THE British consumer recognizes very clearly that war conditions have brought about marked changes in the kind as well as the quantity of meats we eat. The British farmer realizes the changes that have taken place under war controls in the methods of marketing the meat products of his farm. The former may long for the freer choice of kind, quality and price of pre-war times, the latter may wonder how far the present marketing systems foreshadow post-war schemes. Both are in doubt as to the supplies which may be available, and probably neither completely comprehends the broad complexity of the home supply-distribution situation, as it affects the home-market position. Moreover, meat is, in normal times, a foodstuff in which individual preferences for quality, as well as of purpose and price, are allowed wide play. The pie or the pot, the stew or the roast, an 'r' or no 'r' in the month—while such preferences can be signs of the housewife's whim, or her purse, they can also be factors affecting supply and distribution.

At a meeting of the British Society of Animal Production, held on February 21, the meat situation in Great Britain was reviewed from three main aspects, the leading papers being on supplies, by Major W. H. Warman and Mr. R. W. Pomeroy, on carcass quality and grading, by Dr. E. H. Callow, and on the marketing and distribution of home-produced meat and livestock, by Mr. T. J. Shaw.

Before the War, Great Britain consumed, in addition to her own production, about 90-95 per cent of the world's exported surplus of meat. Advances in processing techniques have given us chilled, frozen, boned and canned meats. Whatever the country of origin of the imported meat, its production, processing, grading, transport and distribution were organized towards meeting fairly specific consumer demands, which formed only part of the home-consumption market. In contrast, British home production was all absorbed here in its wide variety of kinds, weights, qualities and prices. Again, owing to, or coincident with, the canalization of the whole industry in exporting countries, the treatment and utilization of edible and inedible offals have become highly developed and contribute to the efficiency and economy of the processing system. In contrast there were, before the War, just over 16½ thousand slaughterhouses, private and municipal, handling roughly 17½ million carcasses which formed the home supply of Great Britain. Further, within Great Britain we have fairly well defined importing and exporting areas, for example, the populous conurbations, as against Scotland and the south-west of England, respectively. So far as stock movements are concerned, there were frequent changes in ownership, not necessarily connected with changes in the condition of the stock, for example, store stock could change hands several times as stores, and partly fattened animals pass from one owner to another without progressing much towards the 'finished' slaughter stage. Also, the question of the effect of movement of fat stock on the quality of the carcass still needs investigation, for the best results and the most efficient supply service, should finished stock be slaughtered in the producing areas or in the consumption areas?

In relation to consumer's preferences the general trends up to 1939 were towards youth rather than to age, to tenderness rather than flavour, and to

lighter weights rather than large cuts. Geographical variations complicated the situation, thus while the Midlands and the north preferred large pork and bacon carcasses, London and the south favoured pork of about 60-80 lb weight. Moreover, even with the wide use of feeding-stuffs imported from overseas, there were marked seasonal fluctuations in the kinds of meat produced here: stall-fed winter beef, autumn grass-fed beef, lamb from the arable flocks of the south in spring, hill lambs and ewe mutton later in the year, and older lambs bred on the hills but fattened on root grounds still later, and on into the first months of the year. Also, in spite of these trends we consumed—we had to, though Lancashire liked to—considerable quantities of cow beef, thereby absorbing the high wastage in our milk-producing herds.

War economy has imposed severe changes on this general structure. The emphasis is on quantity—weight rather than quality. The exclusion of imported feeding-stuffs has placed reliance on home-grown fodders, and revealed a 10 per cent fluctuation in autumn weights between good grazing seasons and bad. Fat stock pass into control at local collecting centres at which the basis of payment is fixed according to grading schedules. Local consumption, apart from supplies originating overseas, is closely related to local production.

The results of these measures of control were soon manifest in all classes of meat, but in one respect the harvest is still to appear—the emphasis on dairy stock which attends the priority given to milk production is judged to lead, with herd wastage still high, to a relative increase in the beasts with inferior capacity to give good beef. Yet nuclei of good beef-breeding types remain, and our presently diminished pig and sheep stocks still contain those types upon which, by appropriate use and from suitable combinations in cross-breeding, the British meat-producing industry could be rebuilt in its multiplicity of kinds and qualities.

If the post-war rehabilitation and form of the meat-producing industry of Britain are to be grossly influenced by the use of imported feeding-stuffs, the questions of available shipping and of available exchange will be prominent. Also, but by no means independent of these, there is the long-term trend for many of those countries which have in the past exported feeding-stuffs to prefer to convert those feeds to carcasses at home, and thus to export, for example, their cereal grains as meat, of higher cash value per unit weight. Behind all, there lie the possible and prospective changes in methods of production and local consumption and demand in the areas from which our meat imports were derived.

This review only touches upon some of the major topics which emerged in the general discussion, it may indicate how the problems are interlaced and the need for much further precise information. Fortunately, there has been a steady accumulation of data which tend to resolve the elusive problems of meat quality and to elucidate the relationships of growth, fattening and food values. In this direction, at least, the scientific principles on which the characteristics of the consumers' demands can be interpreted back to the producer are becoming revealed, and the exposition of the results of recent work in this field at the Low Temperature Research Station at Cambridge made a valuable contribution to the proceedings.

It is hoped that a full report will shortly be published by the Society.

J. E. NICHOLS

A COLTSFOOT PROBLEM

By RICHARD MORSE

SOME time ago, when I was carrying out some investigations concerning the behaviour of plants, I came across the statement, in Sir J. E. Smith's "English Flora" (1829), that the flowers of the coltsfoot (*Tussilago farfara*) are "drooping in the bud". The statement surprised me because, although I had been observing the behaviour of this plant fairly closely over a number of years, both in its wild state and under controlled conditions, I had never once seen it produce flower buds that could in any sense be called drooping. As it was inconceivable that the coltsfoot had changed its behaviour since 1829 I could only conclude that the great botanist was in error, and there the matter was allowed to rest.

Recently, however, I have had occasion to inquire into the subject again, and have been amazed at the number of authors who have, in one form or another, repeated Sir J. E. Smith's statement—a statement which I still believe to be wholly untenable.

In Richard Deakin's monumental "Florigraphia Britannica" (1847), for example, the coltsfoot is described as having "the bud drooping, erect when in flower". Yet Deakin was, presumably, a careful worker with an extensive knowledge of British plants, for we are assured in his fourth volume that the entire series of illustrations, numbering well over 1,600, "are accurate facsimiles engraved from original drawings, made by the Author from the Plants themselves, and carefully coloured after nature".

Again, in the third volume of the five which Anne Pratt devoted to "The Flowering Plants and Ferns of Great Britain" (1856), reference is made to "the drooping unexpanded flower-buds" of this plant, in Hooker's famous "Student's Flora" (1884) appear the words "drooping in bud"; in Johns' "Flowers of the Field" (1919) the phrase takes the form of "drooping before expansion", in Babington's "Manual of British Botany" (1922) the heads are spoken of as being "erect in blossom and seed, drooping before and after flowering", and in Macgregor Skene's "A Flower Book for the Pocket" (1935) occurs the similar statement that "the head droops in the bud and again after flowering".

The above books, it will be observed, cover the period 1829–1935, so that, during more than a hundred years, students of British botany have been asked to accept, in regard to one of our commonest native plants, a statement which, so far as my experience goes, has no foundation in fact, and yet which, so far as I know, has never been discussed or corrected—save for one brief reference that I myself made to it in a broadcast talk some years ago.

What makes the problem stranger still is the fact that several of the books I have mentioned have passed through more than one edition, without, so far as one can tell, any query being raised as to the correctness of the assertions made. Thus my quotations are taken from the second edition of Smith's "Flora", the third edition of Hooker's, the tenth of Babington's "Manual" (edited by A. J. Wilmott), and the thirty-fourth of Johns' "Flowers of the Field" (revised by G. S. Boulger).

Allusions to the coltsfoot's alleged habit of drooping its flower buds, moreover, are by no means confined to books of the more scientific *flora* type. They have crept also into our agricultural, educational and 'popular' botanical literature.

Thus in the Ministry of Agriculture's "Collected Leaflets on Weeds", second edition, 1923, we are told that "at first the flower heads droop, but when they open out they are erect", and H. C. Long, in his "Weeds of Arable Land" (1929), uses precisely the same words.

Similarly, Prof. F. Cavers, in his "Life Histories of Common Plants" (1913)—a book intended chiefly for student teachers—tells us that each flower head "at first droops, but later becomes straight", and in his more advanced work entitled "Botany for Matriculation", revised by L. C. Fox in 1931, those exact words are repeated.

In books of a less scientific character, written chiefly for the general public, the alleged drooping buds of the coltsfoot have been mentioned time and again, for although nutant flower buds are common enough in Nature, this particular story seems to have caught the popular imagination. In James Cundall's "Everyday Book of Natural History" (1866), for example, we read that "at first the flower bud is pendulous, and is thus protected from the rain, as soon, however, as the bloom is ready to unfold to the sun, the flower stalk becomes erect".

John J. Ward, in his "Life Histories of Familiar Plants" (1908), is even more explicit: "The coltsfoot," he says, "guards its pollen almost as a bird does its eggs. When at first the flower stem peeps above the soil, its head droops while the stem elongates. Then, suddenly, the head becomes erect and the florets are exposed."

Again, G. Clark Nuttall, in his fascinating seven-volume work entitled "Wild Flowers as they Grow" (1912), tells us that, in February, the coltsfoot's "hard, thick stem with drooping head pushes up through the earth", while Edward Step, in his "Spring Flowers of the Wild" (1927), says that "until the female florets are ready to open, the stem is bent, so that the head droops".

I must confess that I am much puzzled by the above and other similar references to what I believe to be a wholly fictitious phenomenon. At the time of writing I have no access to *floras* of a date earlier than Sir J. E. Smith's, so I am unable to say whether the belief in the coltsfoot's drooping flower buds goes back beyond his day or not.

Two possible explanations of the prevalence of the belief occur to me. One is that, after someone's original blunder, author has copied author through all these years without ever referring to the plant itself, and the other is that the closed fruit heads have been mistaken for unopened flower heads. The fruit heads 'do', of course, droop for a time after fertilization has taken place. They are, however, so markedly different in appearance from the flower buds that it seems almost incredible that even the veriest amateur could mistake one for the other.

But there is also, of course, the further possibility that my own observations of the plant are at fault. On that point, however, I must leave readers to judge for themselves.

Perhaps I should say, in conclusion, that the omission of several well-known *floras* from the above list must not be taken to mean that they have not been consulted, but simply that I have not yet found one that controverts the statement made by Sir J. E. Smith. There is no reference to the matter, for example, in Withering's "Arrangement of British Plants" (1830), or in Hooker and Arnott's "British Flora" (1850), or in Grindon's "British and Garden

Botany" (1864), or in Bentham's famous "Hand-book" (1924), or in Bonnier's "British Flora" (1925) or in any similar work to which I have access. Brimble, in his "Flowers in Britain" (1944), does not query Smith's statement, but, though he refers to the flower heads being "borne at the ends of thick, erect stalks with hairy bracts", he does not state that the flower buds droop. Furthermore, an illustration shows an erect flower bud.

THE BROAD TAPEWORMS OF MAN, CORMORANTS AND GULLS

J. B. DUGUID and E. M. Sheppard (*J. Path. and Bact.*, 56, 73, 1944). See also *Nature*, 154, 185, 1944) described their discovery of plerocercoids of a *Diphyllbothrium* tapeworm in freshwater trout and sticklebacks in a South Wales reservoir and their work on its life-history. M. D. Hickey and J. R. Harris (*Brit. Med. J.*, 310, Sept 2, 1944) also found *Diphyllbothrium* plerocercoids in trout in the Dublin area, and a *Diphyllbothrium* adult tapeworm in sea-gulls and cormorants there (see also M. D. Hickey, *Brit. Med. J.*, 482, Oct. 7, 1944, and K. Unsworth, *ibid.*, 385, Sept 16, 1944). K. Unsworth (*Ann. Trop. Med. and Parasit.*, 38, 213, 1944) has now published the results of his work on the life-history of the South Wales species.

Starting with a rat infested by Duguid and Sheppard, Unsworth was able to confirm the results obtained by them. He successfully infested the copepods *Cyclops strenuus* and *Diaptomus gracilis*, which Duguid and Sheppard also used, but found that the former was the best first intermediate host. The nauplius larva of *Cyclops* readily ate the coracidia, which were fully developed by the time that the later copepod stages were reached. After 16-20 days of development in *Cyclops*, which Unsworth describes, the *Cyclops* were fed to sticklebacks, in which plerocercoids were obtained, chiefly in cysts on the serous surface of the stomach, under the peritoneum and under the liver capsule. When these sticklebacks were fed to one pike, which is known to be a second intermediate host of *Diphyllbothrium latum* of man, one plerocercoid was obtained from the pike. When plerocercoids from both the infested sticklebacks and the pike were fed to puppies aged 2-3½ months, the adult tapeworm developed in the puppies, which passed eggs in their faeces. Coracidia from these eggs infested *Cyclops*. Unsworth makes the interesting and epidemiologically important suggestion that the overwhelming infestation of the trout in so large an expanse of water in South Wales (100 per cent) was due to the fact that the trout ate sticklebacks which had already infested themselves by eating infested copepods. He supports this suggestion by the observation that the commoner fish hosts which harbour plerocercoids of *Diphyllbothrium* species (for example, perch, pike, wall-eyed pike, trout and burbot) are all fish-eating species, while the less common fish hosts of these plerocercoids (for example, grayling and pollan) eat fish only at times. Unsworth was unable to identify the species of *Diphyllbothrium* with which he was dealing, because he obtained only the scolex and immature anterior segments of the adult from the puppies which he experimentally infested, but, from these, he concluded that the South Wales species studied

by him was too small to be *D. latum* of man. He was also able to infest puppies with plerocercoids sent to him by Hickey from the Dublin area, so that this Dublin species can apparently develop to maturity both in a mammal and in birds (gulls, herring gulls and cormorants). Unsworth concluded that the Irish species is not *Diphyllbothrium latum* of man. The immature stages are not, however, enough for the identification of species of *Diphyllbothrium*.

All these workers sent specimens of the adult tapeworms obtained by them to H. A. Baylis of the British Museum, who concludes (*Brit. Med. J.*, 386, Dec. 30, 1944) that all the tapeworms obtained from the gulls represented one species, and all those from the cormorants another. Comparison of the worms obtained from the experimental mammalian hosts by all the workers led Baylis to conclude that all the workers were dealing in their experiments with a single species, which is probably the old but little-known species *D. dendriticum* (Nitzsch, 1824). In experimental mammalian hosts this species showed slight differences from species found in gulls, probably because the mammal is an abnormal host.

The question raised in the *Lancet* (475, April 8, 1944) that the species found in South Wales might possibly be *D. latum* of man, which does occur in the west of Ireland (see below) and might possibly have been brought to Britain by Polish and Norwegian refugees, as it has been established endemically in North America by immigrants, would seem to have been negated by Baylis's decision. The whole question, however, requires further investigation, for T. E. Gibson (*Brit. Med. J.*, 200, Feb 10, 1945) records yet another infestation of trout in a Northamptonshire reservoir with plerocercoids morphologically similar to those described by Duguid and Sheppard. These failed to infest a guinea pig, but they did infest three rats, which finally threw off the infestation spontaneously, as Unsworth's puppies did. Gibson also found plerocercoids "of a smaller type" in 40 per cent of "smaller fish" in the same reservoir, but attempts to infest rats with these have so far failed (see also T. Hare, *Brit. Med. J.*, 347, March 10, 1945). In addition to this, Dr. Peterson of Yell informed Duguid and Sheppard that a species of *Diphyllbothrium* is also endemic among freshwater trout in some of the Shetland Islands.

With regard to the occurrence of *Diphyllbothrium latum* in man in west Ireland, N. O'Connor (*Brit. Med. J.*, 737, Dec 2, 1944), discussing multiple infestation of man with two types of tapeworm, states that the existence in Ireland of *D. latum* of man was first recorded by O'Farrell (*Lancet*, 1, 466, 1916, 1, 570, 1918; and *Irish J. Med. Sci.*, vi, 95, 1929). Another case was reported by O'Kelly (*Irish J. Med. Sci.*, vi, 188, 1935). The first case of multiple infestation was recorded by O'Farrell (*Irish J. Med. Sci.*, vi, 542, 1930). All these cases came from the Shannon area. O'Connor (*loc. cit.*) himself records the infestation of a husband and wife with *D. latum* in the River Erne area, near lakes not connected with the River Shannon, the wife's infestation being multiple and combined with infestation with *Taenia saginata*. Both ate perch, pike and eels, but no trout; the wife often ate undercooked meat and raw pork. The husband had never been abroad, the wife was born of Irish parents in Glasgow, which town she had visited only twice within the last twenty-three years. G. W. S. Andrews and A. C. Ogilvie (*Brit. Med. J.*, 772, June 3, 1944) record a case of multiple infestation with *Taenia saginata*. G. LAPAGE.

FORTHCOMING EVENTS

Saturday, March 24

ASSOCIATION OF BRITISH ZOOLOGISTS (at the Zoological Society of London, Regent's Park, London, N W 1), at 10 a m—Tenth Annual General Meeting, at 10 30 a m—Dr C F A Pantin, F.R.S. "The Interrelation of Biology Teaching in Schools and Universities", at 2 p m—Dr Stanley Kemp, F.R.S. "Marine Investigations", at 2 45 p m—Dr S A Neave "The Work of the Zoological Society", at 3 30 p m—Mr J C F Fryer "Zoological Interests of the Agricultural Research Council", at 4 15 p m—Dr E B Worthington "Freshwater Investigations"

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 2 30 p m—Mr J H Ridley "An Experimental Approach to Time Lapse Cinematography"

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the SOUTH YORKSHIRE SECTION OF THE ROYAL INSTITUTE OF CHEMISTRY) (at 198 West Street, Sheffield, 1), at 2 30 p m—Dr U R Evans "The Principles governing Corrosion Resistance in Metals and Alloys"

Monday, March 26

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S W 7) at 5 p m—Dr S E Hollingworth "Zones of Rock Flow and Resulting Land Forms"

ROYAL INSTITUTE OF CHEMISTRY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 p m—Dr Harold Moore "Industrial Non-Ferrous Alloys"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Discussion on "The Future of Synthetic and Thermoplastic Insulated Cables" (to be opened by Mr T R Scott)

Tuesday, March 27

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Annual General Meeting Discussion on "The Social Aspects of Television" (to be opened by Capt C H Cazaly)

Thursday, March 29

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W 1), at 5 30 p m—Annual General Meeting

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

CHIEF METALLURGIST by Midland firm to take control under the General Management of the metallurgical side of the production of cold rolled mild alloy and carbon steel strip—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3759 XA) (March 28)

LECTURER IN THE ELECTRICAL ENGINEERING AND PHYSICS DEPARTMENT of the Coventry Technical College—The Director of Education, Education Offices, Coventry (March 29)

ASSISTANT ENTOMOLOGIST (temporary)—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (March 31)

ASSISTANT LECTURER (well-qualified Graduate) FOR MATHEMATICS AND PHYSICS, at the Norwich City College and Art School—The Director of Education, City Hall, Norwich (April 3)

CHAIR OF AGRICULTURAL CHEMISTRY—The Secretary, West of Scotland Agricultural College, 6 Blythwood Square, Glasgow (April 6)

LECTURER (full-time) IN THE DEPARTMENT OF MECHANICAL ENGINEERING of the Leeds College of Technology—The Director of Education, Education Offices, Leeds (April 7)

METALLURGIST GRADUATE for development work in large Steel Foundry in South Midlands—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 2119 XA) (April 9)

CHEMIST on the staff of the WATER POLLUTION-RESEARCH LABORATORY, Watford—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3403 XA) (April 10)

FOOD CHEMIST in the Research Department of a well-known London firm to carry out the analysis of a wide range of food materials packed in metal containers—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 2122 XA) (April 14)

LECTURER IN GENERAL ENGINEERING SUBJECTS, and a LECTURER mainly for ENGINEERING MATHEMATICS—The Registrar, Merchant Venturers Technical College, Bristol 1 (April 15)

WORKS PROCESS CHEMIST for new factory in India—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3705 XA) (April 17)

SENIOR POST as RUBBER RESEARCH CHEMIST with a large Company in the North of England engaged in rubber manufacture—The Ministry of Labour and National Service, Central Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3360 XA) (April 17)

METEOROLOGICAL OFFICER CADETS, Department of Industry and Commerce, Dublin—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (April 20)

ENGINEER FOR THE POSTS AND TELEGRAPHS DEPARTMENT of the Government of Nigeria—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No D 971 A) (April 21)

SENIOR LECTURER (ungraded) IN HISTOLOGY—The Registrar, The University, Liverpool (May 31)

UNIVERSITY CHAIR OF BACTERIOLOGY, tenable at University College Hospital Medical School—The Academic Registrar University of London, c/o Richmond College, Richmond, Surrey (June 25)

HIGH-GRADE TECHNICIAN (male) for laboratory concerned with the construction of moulded applicators individually fitted to patients—The General Superintendent, Christie Hospital and Holt Radium Institute, Withington, Manchester 20

TELECOMMUNICATIONS ENGINEER by S E London engineering firm—The Ministry of Labour and National Service, Appointments Department A 3(A), Sardinia Street, Kingsway, London, W C 2 (quoting Reference No Q 8 S 91)

ASSISTANT SECRETARY—The Royal Photographic Society, 16 Prince's Gate, London, S W 7 (endorsed 'Assistant Secretary')

SPEECH THERAPIST—The Director of Education, Education Offices, Moss Street, Bury, Lancs

READERSHIP IN HUMAN PHYSIOLOGY—The Registrar, University Registry, Oxford

BRITISH EMPIRE SCIENTIFIC CONFERENCE

THE address on "Scientific Co-operation within the British Commonwealth" which Prof. A. V. Hill delivered to the Royal Empire Society on January 31 has claims on the close attention of all scientific workers. In the first place, it gives an account of the actual progress that has been made in implementing co-operation since the committee appointed by the Royal Society reported in 1943. In particular, the Empire Scientific Conference to be called in London by the Royal Society either later this year or, more probably, in 1946, which is one indirect result, not merely of that report, but also of Prof. A. V. Hill's visit to India, of the more recent visit of Indian men of science to Britain and of Sir Henry Tizard's visit to Australia and Canada in 1943, will call for the active support of many more scientific workers than the sixty actual delegates contemplated.

Prof. Hill said that the Conference will probably be held in two parts, the first and more purely scientific gathering being followed by a more official conference for working out concrete plans for submission to the Governments concerned. During the interval, the visitors will travel about Britain in small groups, to see British science, industry, agriculture and medicine in operation, and above all to gain by informal discussion personal acquaintance with each other's problems, programmes and ideas. The value of this informal contact is rightly stressed by Prof. Hill, as in the British Commonwealth Science Committee's report, where it formed the subject of two of the six main recommendations, such contacts are in fact one of the most important things to implement. No organization, as we have urged repeatedly, can be an effective substitute for that full freedom of intercourse and communication, both spoken and written, which for more than five years has been severely limited by war conditions.

If it is true and right that such fundamental freedom should be restored first within the British Commonwealth and as early as possible, it is true also that these proposals to improve and extend imperial co-operation in science are also important in relation to the wider field of scientific co-operation generally, to which Dr. Joseph Needham directed attention in his plea for an international science co-operation service as a functional body parallel with the International Labour Organisation and the Food and Agricultural Office, and on which Sir Henry Dale dwelt at some length in his anniversary address to the Royal Society on November 30. Prof. Hill also emphasizes the importance for international scientific co-operation of such developments in scientific co-operation within the British Empire, and one of his reasons for urging British leadership in this field is the vital importance of building up as rapidly as possible a world organization for sharing the beneficent results of scientific discovery. Above all, it might be fittingly urged at the present time that it is essential to re-establish as early and as fully as

possible those contacts in science which will revive in the harassed peoples of Western Europe the sense of common traditions and heritage in science no less than in law and government, in humanism and in Christianity, with all that such a revival can mean to them as they address themselves to the reconstruction of their national life

While that appears to be the setting in which Prof. Hill rightly views proposals for imperial co-operation in science, the practical tone of his address is unmistakable. His visit to India has convinced him that the best hope of friendly co-operation between India and Britain lies in the scientific, technical and medical fields. It is now probable that the Government of India will set up an Indian Scientific Office in London, and an Indian Scientific Liaison Service may be established with its headquarters in Delhi, its main overseas office in London, and branches in other countries.

Other promising developments are also noted by Prof. Hill, such as the work of the Colonial Research Committee and of the Colonial Products Research Council, and closer contact and co-operation between these bodies and the Dominions and India could scarcely fail to be of mutual advantage in dealing with many scientific, technical, agricultural or medical problems. Again, the attachment of two able scientific advisers to the Middle East Supply Centre is of special interest. In the region covered by the Middle East Supply Centre, science, particularly the biological sciences, could play a dominant part in determining the welfare of the peoples and their relations to the outside world. Problems are encountered in agriculture, irrigation and soil survey, in land conservation and erosion, in geology, meteorology and water supply, in forestry and the preservation or utilization of flora and fauna, in health and nutrition and the like, which are closely analogous to those encountered in other parts of the British Empire, and, further, neglect of the scientific factors will lead to trouble and difficulties which no political astuteness can curb or avoid.

It is, however, in his references to the specific problems in which scientific co-operation within the British Commonwealth is of practical importance that Prof. Hill's address is of the greatest interest. Here he enforces the point that such co-operation alone can provide the solution to important practical problems, some of which, such as that first mentioned by him, namely, the fear of isolation, which deters first-class teachers and research workers from accepting posts in more distant centres, have been raised in recent reports like those of the Colonial Research Committee. Their effects, and means of overcoming it, are obviously problems not for one colony or dominion alone, but for joint consideration and a common policy.

Similarly, the need for quick and frequent personal contacts between research workers in analogous fields is widely recognized, but almost certainly an imperial policy alone can ensure that air transport will supply such contacts regularly for people who are mostly not well paid and have no great political or industrial standing. Again, regular interchange of personnel

between the scientific staffs of universities, industrial firms and research institutions throughout the Commonwealth must largely wait on the formulation of common arrangements, including an appropriate pension system. Allied to this is the problem of organizing and financing the training of young research workers and the higher grades of technologists and workmen by exchange between countries which have special opportunities to offer.

Another group of problems instanced by Prof. Hill as calling for co-operative attention is the combined study of natural resources and conditions—forests, minerals, land utilization, water-power, plants, animals, pests and diseases, and the application of the principles of lend-lease both to their investigation and the utilization of the new knowledge so gained. Here we touch on the question of regional research. Certain regions form natural units for research and development in particular subjects or groups of subjects, although the regions may fall, as in Africa, under the authority of different Governments. The means of securing co-operation and the sharing of effort and expense in such regions require working out, while again, in attempting a concentrated attack on a key problem, we lack the machinery for deciding on the problem and on the method, the scale and the direction of attack and the means by which the expense is to be shared.

Finally, Prof. Hill refers to the question of science and imperial defence, and faces frankly the fact that scientific workers have been troubled in the past as to secrecy being a cover for inefficiency, and the danger of its breeding fear and suspicion. He insists on the need for critical minds and up-to-date methods, for contact with recent scientific discoveries and industrial technique, and for interchange between scientific workers in Government service, in industry and in the universities throughout the British Empire. The relations between civil and military research need to be worked out critically and with imagination, here it may be noted that three of the nine points of imperial defence which Lord Chatfield pressed in the House of Lords on March 7 as requiring investigation closely concern scientific workers. Two of these questions, whether our statesmen require better opportunities of informing themselves on strategical and technical problems of defence, whether service Ministers, when possible, should serve three or four years in their departments so as to master the technical problems, could well be included in the agenda of the proposed conference. The third question, whether the defence of the Empire and the security of the British people could be removed from party strife, or some other means devised to lessen political differences on the basic problems of defence, might also be considered.

Prof. Hill's address shows clearly that a definite practical programme and not mere generalities can be placed before both sessions of the forthcoming Empire Scientific Conference when it meets. There will be ample scope for critical discussion and imaginative planning, but if the Conference is to result in the bold executive action desired, scientific workers must manifest their interest and support in

no uncertain manner in the months preceding its assembly. The application of the methods of biological science, in its widest sense, to the problems of general welfare, and of physical and engineering science to economic and industrial problems, calls for much effort by the individual scientific worker, and, as Prof. Hill points out, may involve facing political as well as scientific and technical issues. Not everyone who recognizes as desirable that fuller and more effective co-operation among men of science for which Prof. Hill pleads will feel as sanguine as he is that such co-operation in the British Commonwealth will appreciably influence the relations of the world as a whole, but it must help rather than hinder international co-operation generally. That the closer co-operation of scientific workers and fuller and freer contacts between them are important factors in the continued advance of science cannot be denied. They are indeed essential conditions in order that mankind may enjoy those higher standards of health and welfare which science has put within our reach. Prof. Hill's address should stir scientific men to take their part not only in thinking about the technical and scientific aspects of the special problems he has indicated for consideration by the Empire Scientific Conference, but also, and equally important, in educating their fellow-citizens as to what is at stake. They can prepare the way for the measures required to implement such co-operation, and to establish and safeguard that code of common ethical standards which, as Prof. Hill so emphatically urged, will be a safeguard against the abuse of science either in peace or in war.

A PHYSICIST LOOKS AT GENETICS

What is Life?

The Physical Aspect of the Living Cell. By Prof. Erwin Schrodinger (Based on Lectures delivered under the auspices of the Dublin Institute for Advanced Studies at Trinity College, Dublin, in February 1943) Pp viii+91+4 plates (Cambridge At the University Press, 1944) 6s net

AS a result of the War, many scientific workers have been too busy with the applications of science to keep up even with the development of their own branch. Schrodinger, as an exile in neutral Eire, has found the leisure to study another, namely, genetics, which he describes as "a new branch of science, easily the most interesting of our days." I wonder if posterity will find crossing-over as interesting as exchange energy, or mutation as atomic transition. However this may be, every geneticist will be interested in Schrodinger's approach to his or her science.

Schrodinger sets out to answer the question "How can the events in space and time which take place within the spatial boundary of a living organism be accounted for by physics and chemistry?" He believes that they can, but not by present-day physics and chemistry. Accepting the view, first, I think, put forward by Koltsch, that a chromosome is a giant molecule, Schrodinger describes it as an aperiodic crystal. Thus it may be expected to have some of the properties of a crystal, including that of

self-reproduction, and yet to be of so highly complex a structure that it can act as a "code-script" for the development of an organism. He thinks that just because a gene is of molecular dimensions, and there are only one or two genes of a kind per cell, one cannot apply statistical mechanics to the behaviour of genes. This is perhaps not quite certain; for an organic catalyst can, in favourable circumstances, transform more than 100,000 substrate molecules per second. If genes are catalysts of this order of activity, even a single gene requires statistical treatment.

Much of the book is devoted to mutation, and the author not merely accepts Delbruck's account of this process, but also writes that "If the Delbruck picture fails, we would have to give up further attempts." This seems a rash statement from a quantum physicist. The modern 'picture' of an atom is not superficially very like Bohr's picture, for discrete orbits of electrons have been replaced by a continuous probability distribution. Yet Bohr's theory explained so much that it was hard to believe that it would be so greatly modified.

Actually I believe that the Delbruck picture will have to be modified profoundly, for the following reason. Schrodinger (p. 65) states that the single event which produces a mutation "must be an ionization or similar process." Lea and Catchside, in unpublished work communicated to the Genetical Society, which they very kindly allow me to quote, produce strong evidence that many, if not all, lethal mutations produced by irradiating *Drosophila* spermatozoa are due to chromosome breakage followed by restitution, and in *Tradescantia* they¹ calculate that "at least 17 ionizations must be produced in a chromatid to cause a break". In spite of this they think that the 'target-area' gives the size of the gene correctly. In fact, as so often in quantum mechanics, a simple theory gave fairly correct results, but nevertheless had to be modified.

Again (p. 64), the fact that the mutation-rate of wild-type genes is more enhanced by temperature than that of less-stable mutant genes is neatly explained on quantum-mechanical grounds. But Fabergé and Beale² found that the mutation-rate of a very unstable gene actually fell off at high temperatures. Perhaps there are more things in chromosomes than are dreamt of even in wave mechanics.

I make these criticisms not from any desire to denigrate the book before me, but because many geneticists will read it, and all of them should. And not only geneticists. The physiologist who can assimilate the idea that a living organism feeds on negative entropy will come back to the study of metabolism with a slightly novel set of questions to ask. Nevertheless, a whole series of biological problems are not raised. Many biologists have found it impossible to explain the facts of organic regulation on mechanistic lines. Prof. Schrodinger's views on genetics are so interesting that I hope he will tackle this problem, too, in another book. In a living organism we find a hierarchy, so to say, of normal conditions. A man does his best to keep the partial pressure of carbon dioxide and the concentration of bicarbonate ions in his plasma constant. If he fails in either respect, he will use his lungs, kidneys, or both, to bring their ratio, and therefore his pH, back towards normal. But even pH is less important than an adequate oxygen supply. And so on. A mathematical physicist might be able to find physical analogies, or even explanations, for such facts as these.

A mechanist must either give a mechanistic account of mind, or turn a somersault. In his epilogue, Schrodinger does the latter with very great elegance, and adopts a metaphysical position which is roughly that of Samkara Acharya. There is only one soul, the difference between yours and mine being an illusion. I think that here, too, the history of quantum mechanics suggests that the truth may be somewhere between mechanism and advaita metaphysics. There is no way of distinguishing between the two electrons in a hydrogen molecule, you cannot put a spot of red paint on one of them. This fact makes a difference to their behaviour. Nevertheless there are two electrons, not one. Perhaps the relation between two souls is a little more like that between two electrons than between two tables, and these philosophical problems will be solved, or at least transformed, when our descendants learn to apply to mind the kind of analysis which Schrodinger has applied to matter.

However that may be, the book is one to which one comes back again and again. I have lent it to several genetical colleagues, and the verdict has been uniformly favourable. We may disagree with details, or even with fundamental principles, but we cannot stop reading it before the end. Unfortunately, it contains only 93 pages. There are 93 elements, but 738 isotopes have so far been described. Perhaps we may hope for a book of 738 pages on biology in general. Prof Schrodinger need not doubt that it will find readers.

PSYCHOLOGY OR RELIGION?

The Lady of the Hare

Being a Study in the Healing Power of Dreams. By Dr John Layard. Pp 277 (London: Faber and Faber, Ltd., 1944.) 12s 6d net.

THIS volume, which is attractively produced and well illustrated, purports to be the first verbatim account ever published of a dream-analysis on Jungian lines. (Jung's numerous own seminar accounts of dream analyses published in limited number for the use of his students may not have come to the notice of the author.) In Part 1, twelve professional sessions are described in which a number of dreams and so-called visions of a woman patient were discussed. This is followed by a brief theoretical discussion, a summary of the dream process, and a description of the subsequent remarkable development of the patient's mentally defective daughter. Since one dream of the patient contains the figure of a hare which she is meant to kill or sacrifice, Part 2 of the book deals with the mythology of the hare, and the author follows up the hare motive in myths and folklore of India, China, Egypt, Africa, North America, Europe and classical antiquity. In Part 3, more dreams about hares and rabbits are communicated.

As Dr Layard, the anthropologist, has the well-known informative "Stone Men of Malekula" to his credit, one opens this book by Dr Layard, the psychologist, with high expectations of finding a full and well-substantiated account of a case-history illustrating the practice of Jung's analytical psychology. The author, however, does not fulfil these expectations, but expounds his own psychotherapeutic technique and healing powers, which bear little

relation to Jung's practice and theory of analytical psychology. The result is a book which will fill the informed student of analytical psychology with dismay and induce the uninformed reader to identify the Jungian method with that of the author, which is a fallacious assumption.

Jung defines the aim of analytical psychology as that of individuation. The author defines it (p. 18) as that of salvation, thereby discarding the scientific phenomenological approach of Jung, identifying psychology with religion and the psychologist with the priest or magician (the patient's "You are a minister of God", p. 47), in defiance of the teachings of Jung (cf. "The Relations between the Ego and the Unconscious"). Nor is the author following Jungian practice in treating the transference of the "Saviour Archetype" by "disclaiming it on every occasion when it arose". "emphasizing the obvious unsuitability of any such personal projection" (p. 82), for according to Jung (*loc. cit.*) the problem of transference defies rationalizations of this kind. However, most alien to the point of view of analytical psychology, which refrains from making sweeping, scientifically untenable claims and conforms to the standards expected from proper clinical psychological research, are two basic aspects of the account given of dream-analysis which reveal the author's unfamiliarity with, or disregard of, the Jungian practice of dream-analysis.

One is that the author gives the unsuspecting reader the impression—and appears to share it himself—that the twelve interviews described, comprising the discussion of twenty-five dreams and visions and covering a period of about two and a half months, perfected a cure comparable with that attained in the gradual process of growth facilitated by a proper analysis. His insistence on quick results ("The deeper the analysis the quicker the cure", p. 20, "The whole interview had lasted just $\frac{1}{2}$ hour, but it had been enough", p. 36; "As last week, the whole interview lasted less than $\frac{3}{4}$ of an hour", p. 58) betrays the anthropologist's fascination for the magic practices of the medicine man, while his belief in miraculous and spectacular healing reminds one of the claims of faith-healers. The claim that his twelve-interview treatment is representative of Jungian practice shows grave lack of knowledge of the work of Jung and his school.

The other main aspect incompatible with Jungian principles and practice is the victimization of the patient during the sessions, as described. Even granting that the expression "verbatim account" may be an exaggeration and should not be taken literally, there remains the fact that undue prominence is given to the author's intuitions about the dreams and his suggestions to the patient, while the patient's own spontaneous associations are partly not admitted and partly not related. This practice is alien to that expounded by Jung.

Thus the main part of the book gives the reader insight into Dr Layard's psychotherapeutic technique and powers, but the reader must beware of confusing this, as the author has done, with the technique of Jungian analysis.

In Part 2, when collecting the hare motive as found in mythological material of primitives and the ancients, Dr Layard, the anthropologist, is at work once more, and this part, though of little import for the case described, forms a work of reference on the hare motive which will be very useful for the student of mythology.

The author would be well advised to write the promised second volume without reference to Jung's analytical psychology, for the reference to Jung is apt to create confusion and do a disservice to Jung, and incidentally to the author himself

H J JACOBY

BROADCASTS ON FARMING

'Farming Talks'

By W S Mansfield Pp 119+8 plates (Worcester Littlebury and Co, Ltd, n d) 7s. 6d net.

Farming To-day Broadcasts

Vol 2 A Series of Agricultural Education and Technical Development Broadcast Talks Pp 130+12 plates (Worcester Littlebury and Co, Ltd, n d) 7s 6d net

THESE two groups of farming broadcasts are presented without alteration in form, a procedure which has both advantages and demerits. For those who did not hear the original talk or discussion, the structure, particularly when dialogue, does not make for easy reading and there are occasional difficulties of meaning. Those who have heard most of the broadcasts—and they will probably be the majority of readers—will be able to recapture the atmosphere and enjoy again the accents of the speakers.

Since 1937 Mr Mansfield has been a regular and notable contributor to B B C broadcasts on farming topics—he takes part in six of the discussions in the second series of 'Farming To-day'. The talks and discussions of this second volume were given in 1943 and the first quarter of 1944, and are arranged chronologically. About half of the 'Farming Talks' were given before the War, and the remainder nearly all in its first two years. The illustrations in both volumes are well reproduced, their function is decorative, having no special reference to textual matter.

War needs have changed the character of these broadcasts. Mr Mansfield's earlier talks were aimed at a wider audience, though intended for farmers, they were designed also to interest the townsman in the land and its problems. There are discussions—for example, one with Dr Sanders on high and low farming—but mainly they are straight talks, with at the end perhaps a short dialogue with his farm bailiff or rat-catcher, for illustrative purposes. In these he succeeds very well in catching something of the spirit of the land. Talking, in 1938, on successful farming, he quotes Xenophon to the effect that the difference between those who succeed and those who do not is a difference not of knowledge but of care in management. To the extent of conceding that knowledge, experience, good land and adequate capital are not enough without character—and especially adaptability to changing conditions—Mr Mansfield agrees.

Great changes have been forced on British agriculture by war needs, after the War there must be a further change, which, whatever else it may be, will not be a reversion to the conditions of 1939. The war-time broadcasts have been educational and propagandist in character, aiming at spreading new ideas, publicizing the results of agricultural research, and generally supplementing the work of the war agricultural committees.

Some of the contributors to 'Farming To-day Broadcasts' are farmers, some are specialists. Welsh

hill land improvement, sugar beet, haymaking, care of machinery and composting straw are among the topics of discussion. Not all the talks are concerned with immediate needs, particularly where livestock are involved (because of their low reproductive rate) there must be long-term planning. There has been a great decline in the sheep population of Britain. Four discussions deal with hill sheep, arable and grassland flocks, and disease, and consider probable sources and methods of management in post-war agriculture. Naturally none of the subjects is treated at any great length.

HYDRAULICS IN THEORY AND PRACTICE

A Treatise on Applied Hydraulics

By Prof Herbert Addison Third edition, revised and enlarged Pp viii+614 (London Chapman and Hall, Ltd, 1944) 32s net

PROF ADDISON explains, in his preface, that his aim in writing this book was to present a compact summary of the fundamental principles of hydraulics and the manner in which they are applied, and he expresses the hope that the book will meet the requirements of three classes of readers—the engineer in practice who desires to keep in touch with modern developments in hydraulics, the general student of engineering and the student who wishes to specialize in the subject and who desires a reliable basis for further study. In these aims he has succeeded admirably.

The first part of the book deals with theoretical principles and the second with practical applications, the whole being extremely well illustrated by diagrams and photographs. A striking feature is the arrangement of the subject-matter, thus the numerous worked examples, and problems for solution by the student, are collected together towards the end of the book and reference is made to them when illustration is necessary. Such arrangement has the advantage that the continuity of the text is not interrupted and, in any section, the student may obtain, in the first instance, a clear and concise statement of the engineering aspect of each problem as a background to his study of the theoretical discussion.

The second part of the book introduces a wide range of applications, including the flow of water in pipes, channels and streams, the control of water, viscous flow, hydraulic turbines, pumping machinery, power transmission and hydraulic measurements.

From the method of presentation there is ample evidence not only of Prof Addison's breadth of knowledge, but also of his experience as a teacher and his appreciation of the problems which confront the teacher and student alike, in dealing with the complexities of a subject in which it is particularly difficult to apply the results of theoretical investigation to the conditions which prevail in practice.

While this is an excellent text-book for the use of students preparing for university and institution examinations, it is much more than that, for it summarizes the results of modern research, is equipped with a comprehensive bibliography of recent publications, and its descriptions and illustrations refer to up-to-date installations. Civil, mechanical and electrical engineers will find it a most complete and informative book of reference on hydraulic engineering.

J. B. TODD

Your Daily Bread

By Doris Grant Pp 94 (London Faber and Faber, Ltd., 1944) 4s 6d net

THIS little book covers a lot of ground. Essentially, Miss Grant sets out to prove that white bread—or “murdered bread” as she prefers to call it—is responsible for much of our poor and indifferent health, and she pleads the case for wholemeal bread as the remedy. The book contains much scientific material, and although some of it is not very critical, the case is skilfully presented. It is suggested, for example, that because nicotinic acid helps to create skin beauty, “one of the best and easiest ways of ensuring a flawless complexion is to eat whole-wheat bread”.

A section of the book deals with the place of bread in a balanced diet and gives specimen menus. Miss Grant abhors imported or processed foods of any kind, and she is supported in this by Sir Albert Howard, who contributes a chapter on the importance of fertile soil for the production of best-quality wheat. Sir Albert includes all canned foods, chilled meat and frozen fish with white bread as “murdered foods”, and claims that they are responsible for the poor physique of our urban population. Further, he condemns the use of artificial manures of all kinds. Another chapter reproduces the Cheshire memorandum, a statement by a number of medical practitioners from that county on some general aspects of nutrition including the arguments in favour of wholemeal bread.

The book concludes with a number of recipes for cakes, scones, biscuits, etc., using wholemeal flour. Perhaps the most important recipe is that for the ‘Grant loaf’. A sample was made for the reviewer, strictly according to instructions but using ordinary salt and cane sugar, by a skilled baker. When eaten at tea by a family of four, two preferred it to National bread, however, when two days old, one only was still enthusiastic. It is not easy to break dietary habits.

School Physics

By T M Yarwood Part 2 Pp x + 438 (London Macmillan and Co., Ltd., 1945) 7s 6d

THIS book includes all that is required for the various School Certificate examinations. Together with the previous more elementary part, it provides the basis for a sound school course in physics. Good features are the frequent references to the applications of science to everyday life, the inclusion of a chapter on radio, and the numerous problems solved in the text.

In the reviewer’s opinion, however, it is a mistake to cover the whole of physics in two books. The inevitable result is that the presentation is not so attractive as in well-known series of books covering the same ground. Having attempted it, dullness might have been avoided by the lavish use of half-tones, but there are only half a dozen in the 400 pages.

There are a few slips and inadequacies two may be mentioned. On p 73 it is said that the gas ejected from a jet-propelled plane “presses on the air behind the aeroplane, and the machine is thus pushed forward”. On p 131, stress is laid on the thermal capacities of water and mercury, water and sand, etc. The effect of their relative densities should also be mentioned when comparing the thermal capacities of two bodies, for example, two thermometers.

J P STEPHENSON

On a Class of Linear Transformations Connected with Group Representations

By Lars Gårding (Meddelanden från Universitets Matematiska Seminarium, Band 6) Pp 125 (Lund C W K Gleerup, 1944) n p

BASIC spinors are defined with reference to the equation $T^{-1}\gamma_i T = \Sigma a_{ij}\gamma_j$, where γ_i represents a set of anti-commuting matrices, $[a_{ij}]$ is the matrix of an orthogonal transformation, and T is the matrix of transformation for basic spinors. Dirac’s equation for the electron is of the form $\nabla^2\psi = k^2\psi$, where ψ is a basic spinor. The same equation, but with ψ representing quantities of other types, occurs in other contexts in quantum theory and nuclear physics.

Dr Gårding sets himself the problem of investigating the generalized equation $S^{-1}V_i T = \Sigma a_{ij}V_j$, where V_i represents a finite set of matrices, and S , T , and $[a_{ij}]$ are any representations of a continuous group, in particular of the orthogonal group with $S = T$. His applications are concerned mainly with the solutions of $\nabla^2\psi = k^2\psi$ for different types of quantity ψ .

In many instances the constructions seem unnecessarily elaborate, and this makes the thesis difficult to read. It would appear very probable that the principal conclusions could be obtained in a more direct manner. Nevertheless, the thesis is very interesting and suggestive, and many detailed formulæ are obtained which in themselves have some value. It shows considerable mastery over many aspects of group representational theory, and many known results are recapitulated incidentally.

The work shows considerable promise, and future publications by the author will be awaited with interest.

D E LITTLEWOOD

Principles of Magnetic Crack Detection

A Practical Treatise specially written for those about to Operate the Process. By H Bevan Swift Pp vi + 105 (London E and F N Spon, Ltd., 1944) 10s 6d

MAGNETIC methods have proved useful in the detection of cracks, too inconspicuous to be seen without such aid, in steel. This handbook is in the main a description of the apparatus for carrying out such tests in the laboratory or workshop. Several commercial forms of instrument are described, with a general account of the principles of the method. In one type a direct current is passed through the object being tested, and the concentrated field at the edges of a crack is made visible by pouring on a suspension in light paraffin of a highly magnetic preparation of iron oxide. In the second type, suitable for steels with a higher retentivity, a heavy but very short electrical impulse is sent through the object, and the ink is applied afterwards. Only actual experience enables an observer to decide on the significance of the indications given by the magnetic ink, and to distinguish between cracks and accumulations of the magnetic material caused by sudden changes of section or by casual scratches. Methods of demagnetization have to be applied when, for example, parts for aircraft are being tested.

There is a short note on the testing of bars by comparison with a standard, using a null method. Actually, this plan has been used extensively in some works for the testing of small parts, such as chain links, for correct heat treatment, a definite relation being found between the hardness and the magnetic properties, so that a very rapid sorting of correctly from incorrectly treated parts is possible.

ARTIFICIAL PRODUCTION OF COAT COLOUR IN THE ALBINO RAT

ITS RELATION TO PATTERN IN THE GROWTH OF HAIR

By DR. ALEXANDER HADDOW, DR. L. A. ELSON and DR. EDNA M. F. ROE

Chester Beatty Research Institute, Royal Cancer Hospital (Free), London

DR. K. M. RUDALL

Textile Physics Laboratory, University of Leeds

AND

G. M. TIMMIS

Imperial Chemical Industries, Ltd., Manchester

DURING experiments on growth, which were designed to test the action of a series of flavins, a hitherto undescribed property was encountered in one of these compounds (9-phenyl-5 : 6-benzo-*iso*-alloxazine¹), the structure of which is shown in Fig. 1. Quite unexpectedly, injection of 20–30 mgm. of this substance, in albino rats, produced an orange-yellow pigmentation of the hair. It was then observed that the coloration so produced is usually restricted to certain areas of the coat, in a way which varies considerably from one rat to another, but nevertheless conforms to a characteristic type of pattern (Fig. 2), of which the most striking feature is a pronounced degree of symmetry about the longitudinal axis. Study of some scores of similarly injected rats from the same albino colony soon revealed the regular recurrence of pattern types, which it was comparatively easy to arrange as a roughly transitional series: these facts conveyed a strong impression of a certain unity of design, in which each individual represents only one stage in a continuous rhythmic process. That the pattern which may be elicited in individual animals is variable was proved by administration of the compound at intervals of one to three weeks, fresh zones of colour appearing in response to each such injection: hence its form depends (in the majority of cases at least) upon a fluctuating process, and not upon one which is fixed, or pre-determined, genetically or otherwise.

Relation of Pattern to the Growth of Hair

That the developmental process involved might concern the regeneration of hair was suggested by a number of facts. Dry² recorded that growth of hair on the flank of the rat may be restricted to a strip about half an inch wide running along the length of the body: such a band of growing hair had frequently been observed by the present authors in earlier work,

and the irregular distribution of hair regeneration in the rat had also been noted by others^{3,4}. In experiments to test this hypothesis—that the pattern-form is determined by the growth of hair—normal rats were shorn dorsally and laterally from the level of the ears to the root of the tail and down to a low ventro-lateral level, and the subsequent course of regeneration was then plotted, at intervals of a few days. At once it be-

9-phenyl-5 : 6-benzo-*iso*-alloxazine
Fig. 1.

came apparent (Fig. 3) that only limited regions of the coat are regenerating hair at any given moment, that these areas are disposed in a symmetrical arrangement similar to the patterns revealed by injection of the specific *iso*-alloxazine, and that their variety is due to the varying rate of progress of the growth-wave front. It was further observed that the advance of the wave is in general more rapid on the back and belly, and slower on the sides, and that the growth-wave cycle, traversing the surface of the body, is complete in a minimum period of approximately six weeks. But the whole cycle may be greatly disturbed, and prolonged, by factors connected with nutrition, season, lactation, and age. From these experiments it seems probable that the rat coat is replenished by a complex series of regular waves; in individual animals the pattern may be modified by

Fig. 2. COLOUR PATTERN PRODUCED BY TWO INTRA-PERITONEAL INJECTIONS (AT AN INTERVAL OF ONE WEEK) OF 25 MGm. 9-PHENYL-5 : 6-BENZO-*iso*-ALLOXAZINE IN ARACHIS OIL (FILTER EMPLOYED: ILFORD TRICOLOUR BLUE No. 304).

isolated bursts of growth, or by a sudden subsidence.

It now appeared that the hair coloration produced by 9-phenyl-5 : 6-benzo-*iso*-alloxazine is due to a localization, in growing hair but not in non-growing areas, of the injected compound or of a derivative; and evidence confirmatory of the latter point was soon obtained from direct examination of the hair pigment itself.

Nature of the Hair Pigment

In order to isolate the pigment, several grams of the coloured hair were treated with glacial acetic acid; after addition of chloroform, removal of the acid with water, and chromatography of the chloroform extract, the hair pigment was obtained as an orange-yellow fluorescing substance, the ultra-violet absorption spectrum of which showed the presence of the injected compound or of some simple derivative which is spectroscopically indistinguishable under the condi-

Fig. 3. REGENERATION OF HAIR AT 3, 8, 14, 30 AND 35 DAYS AFTER SHEARING THE AREA OF ABCD. SIMILARLY HATCHED AREAS ARE THOSE IN WHICH HAIR IS GROWING AT THE SAME TIME AND IN WHICH THE ALLOXAZINE PIGMENTATION WOULD DEVELOP IN RESPONSE TO ADMINISTRATION OF THE COMPOUND AT ABOUT THAT TIME.

tions employed; by this means it was calculated that there is approximately 0.1–0.2 mgm. of 9-phenyl-5:6-benzo-*iso*-alloxazine in the fluorescent eluate obtained from 1 gm. of hair.

The derivation of the hair pigment from the administered compound had thus been virtually proved, and an explanation obtained of its selective localization, namely, to those tracts of hair alone which are in active growth at the time of injection.

Mechanism of Localization

It was next found possible to indicate the mechanism of such localization from a study of the blood capillary circulation to the hair follicles, in rats which had previously been sheared as described. Visualization of the capillary system, in permanent preparations (achieved by the injection, under ether anaesthesia, of 1 ml. of a 15 per cent solution of chlorazol sky blue FFS into the femoral vein), revealed that by far the greatest density of capillaries occurs in those positions which correspond to the advancing edge of the growing hair, with a sharp cut-off at the receding edge. This observation is believed to be entirely new; it is, of course, highly suggestive, not only of the means by which the growth-wave progresses, but also of the way in which the circulating pigment enters the cuticle and cortex of the growing fibre. It would seem reasonable to infer that the constantly moving patterns of hair-growth appear in response to rhythmic alterations in the distribution of blood to the hair follicles, so that, as capillaries close down, the growth of hair recedes, while at the same time capillary activity is apparently spreading to other regions, in which the follicles at once react, and growth of hair is resumed. It is also likely that the pigment enters growing areas partly because these are the only ones in sufficiently active interchange with the general circulation. Such an interpretation was strongly supported by capillary

visualization in rats which had been both sheared and injected with 9-phenyl-5:6-benzo-*iso*-alloxazine, all these procedures being carried out within one week in order to obtain near correspondence. By this means it was possible to study capillary density, the position of the wave front, and the pigmented tract simultaneously, in a single preparation, and to show that they have precisely the same distribution.

Some attention has also been paid to the mode of chemical transport of the compound, and particularly whether this might be brought about in combination with cystine in the elaboration of keratin. Direct evidence is here less easily obtained, but it may be said that the alteration in urinary sulphur partition produced by injection of 9-phenyl-5:6-benzo-*iso*-alloxazine (in an experiment by Dr. F. L. Warren) is at least consistent with conjugation between the pigment and cysteine.

Chemical Specificity: Coloration and Absorption

The phenomenon was at first believed to depend upon a high degree of chemical specificity. No pigmentation had been noted in earlier and similar experiments with the first five members of the homologous series of 9-alkyl-5:6-benzo-*iso*-alloxazines, that is, those compounds in which the phenyl group of 9-phenyl-5:6-benzo-*iso*-alloxazine is replaced by a methyl, ethyl, *n*-propyl, *n*-butyl, or *n*-amyl group. Closer inspection has, however, shown that all these compounds do in fact produce slight traces of coat coloration, which is nevertheless far short of the intensity resulting from 9-phenyl-5:6-benzo-*iso*-alloxazine. A very satisfactory direct correlation has been established between the intensity of coloration produced and the excretion of a pigment, for the most part identical with the administered substance, in the faeces and urine: from this it is obvious that the outstandingly active compound is equally outstanding in its rate of elimination. Assuming the rate of output reflects the rate of uptake of the compound from the tissues, it is concluded that the intensity of coloration produced is correlated, within this series, with ease of absorption, and that such is conferred by the phenyl group to a marked degree. Among related substances, a slight degree of hair pigmentation is induced by 9-phenyl-*iso*-alloxazine, that is, the compound differing from 9-phenyl-5:6-benzo-*iso*-alloxazine in the absence of the angular ring.

Other Aspects

In a topic of such obvious and broad interest from both the biochemical and the zoological aspects, many other features have emerged, or are being investigated, relating to the physiology of hair growth and animal pigmentation. For the purpose of the present communication some of these may be summarized more shortly. It has been noticed, for example, that for any group of follicles, both capillary activity and hair growth are inhibited for some time after the cessation of a period of activity. With reference to this, an attempt is being made to determine the effect on the wave front of areas which have been rendered out of phase by epilation. There is also some evidence that the capillary waves move not continuously but in a series of pulses, and it is an interesting possibility that this rhythmic activity of the capillary wave front may be related to some similar rhythm in the sympathetic nervous system. This is especially so in view of a suggestion, based on the observation that concave sections of the wave

front occasionally tend to 'fill', and so smooth themselves out, more rapidly than the entire front advances, that the movement is dependent upon the release in the tissues of a chemical substance, which might accordingly reach a higher local concentration in the troughs of the pattern than at the crests. However, such a neurohumoral mechanism still remains to be fully tested by experiment.

The pigmentation phenomenon is being studied further in relation to sex, age, genetic constitution, and species. It has been noted that the intensity of pigmentation following injection tends to be slightly greater, other factors being equal, in male rats than in females. In practically all cases the pattern evoked was of similar type and behaviour in hooded rats (of constitution *CCss*), in coloured rats (*CCSS*), and in albino rats of the constitutions *ccss* and *ccSS*—thus there is no indication that the pattern revealed is related to a genetically determined pattern already present, whether manifest or latent. (For assistance in the isolation of these genotypes we are much indebted to Dr P. C. Koller.) Some allusion may also be made to the possible affinity between the capillary and hair-growth pattern in the rat, and striped or banded pigmented patterns in other mammals.

So far as the behaviour of 9-phenyl-5,6-benzo-*iso*-alloxazine in other species is concerned, only brief mention may here be made of its effects in mice. No action of any kind has been observed following administration of the compound (by injection or by feeding) to stock albinos or mice of the *R* III and Strong *A* pure lines. On the other hand, prolonged feeding (over many months) to black-eyed or so-called 'dominant' whites has apparently resulted in a slow increase of yellow pigmentation, although only very slight in intensity, confined to the dorsum and flanks. It by no means follows that the *iso*-alloxazine most effectively absorbed by growing rat hair is likely to be the most penetrating in other species, and having regard to the interest which would attend any extension of the phenomenon to mice, other compounds are being studied with this consideration in view.

Lastly, from the chemical side alone a wide field of inquiry can be opened up. How far molecular constitution may be modified, while still retaining this curious property, and how far the colour of the pigments themselves can be varied, within these limits, have so far only been studied in a very preliminary way. However, data have already been obtained concerning various colourless degradation and oxidation products of 9-phenyl-5,6-benzo-*iso*-alloxazine, which may conceivably have some bearing upon the chemical basis of albinism. Also, it may be of importance to relate these synthetic compounds to the so-called 'xanthic' pigments, of both known and unknown molecular structure (and including the butterfly wing pigments and other pterins), such as possess physiological importance or have a wide distribution in Nature.

Poulton, in his book on the colours of animals⁵, directed attention to what he classified as 'non-significant' colours, that is, pigments without physiological value in respect of their colour as such. But he also stressed their importance, as the material out of which natural selection can create 'significant' colours, namely, those with special functions in protection, concealment, mimicry, adornment, and so on. We may conjecture that if a mammalian species, in which the growth of hair followed the same rules

as apply in the rat, were to form a pigmented metabolic product with the properties of the *iso*-alloxazine, coat colour would inevitably result. It is then a legitimate surmise, following Poulton, whether such an arrangement might not become genetically fixed, or subject to natural selection, and thus confer some permanent biological advantage, protective or otherwise. This, however, is a matter of speculation. So far we can only say that the alloxazine colouring is adventitious and artificial, but may be potentially significant, in Poulton's sense, as well.

It is hoped in due course to publish a fuller account of this investigation elsewhere.

DORMANCY IN BRITISH-GROWN WHEAT

By E. N. GREER and J. B. HUTCHINSON

Cereals Research Station, Ministry of Food, St. Albans

BEFORE the War, only a relatively small percentage of the wheat used in bread in the British Isles was home-grown. During the War, however, the acreage of home-grown wheat has more than doubled, and a large proportion of this wheat is used in bread-making grists (on occasions as much as 60 per cent of the grist). This in turn has raised the question of the most suitable varieties for bread-making. Unfortunately, this is not a simple question to answer since the quality of wheat is influenced by season and environment. Nevertheless, the National Institute of Agricultural Botany has recently issued a report giving broad recommendations based on the results of trials carried out over a long series of years.

In 1941 and particularly in 1944, a further problem arose. The weather at harvesting was unusually wet, and as a result much of the wheat sprouted in the field. As is well known, the effects of sprouting on the commercial value of a wheat crop are serious. Not only is the grain useless for seed, but also its value for milling purposes is greatly impaired. The enzymes produced during germination reduce the baking quality of flour, giving rise to undesirable characteristics in dough and bread which cannot be rectified by treatment. The diastatic activity of a wheat (normally expressed as the 'maltose figure') is a measure of the extent of germination, and in an effort to lessen the damaging effects of sprouted home-grown wheat the Ministry of Food issued instructions that no wheat must be used with a maltose figure exceeding 3 per cent. Even so, this type of damage in varying degree has been evident in much of our bread—the crumb is doughy and the loaf cuts badly—and in routine surveys of the quality of commercial bread during November and December last, as much as 25 per cent of the bread was affected.

The ease with which a freshly harvested seed germinates is linked up with the extent to which it shows dormancy, some seeds will only germinate after a prolonged period of dry storage. The phenomenon has received attention from several investigators, notably Harrington¹ and Crocker². Crocker

has pointed out that most species of wild seed can show a very prolonged dormancy which serves as a natural protection for the preservation of the species. In cultivated varieties the phenomenon is far less evident but still persists in varying degrees. The frequent occurrence of dormancy in home-grown new crop barley, especially in the colder and damper north of Britain, is well known to maltsters, who find it necessary to dry such grain in a kiln and store it over a period of weeks or even months to secure the rapid and even germination essential to their process. Bishop³ has also recently recalled the observation of Duchartre⁴ on the variations of the germinative energy of barley at, and about, harvest time. Duchartre noted that while barley grain in the milk stage was capable of germinating readily under suitable conditions, upon ripening the power of rapid germination steadily diminished, passed through a minimum, and thereafter improved to a maximum from which it was very slowly reduced with age. It is, therefore, usual to distinguish the ripe stage of barley, at which it is ready for harvest, from the so-called mature stage at which it is able to germinate readily, and the recovery process is termed 'maturation'. The length of the dormancy period and the rate of maturation are usually considered to be a function of the conditions of temperature and moisture content in which the grain finds itself, a warm, dry condition hastens maturation, and conversely cold and damp retard it. However, in any sample of dormant grain, representatives of all stages of dormancy are usually to be found, hence germination tests show uneven response with time, and are, of course, liable to considerable sampling error.

Little attention has hitherto been paid to the study of dormancy in English wheat. In general, it appears to be less evident than in barley, though from our own observations it follows a similar course. During the past season, we have been fortunate enough to obtain from Rothamsted Experimental Station samples of both Als and Vilmorm wheats during seven weeks covering a period immediately prior to and following upon the cutting of the crop. Many grains of the earliest samples when first removed from the ear and planted showed rapid germination, a capacity which they lost almost entirely after a short period of drying in the sun. The later samples of wheat showed pronounced dormancy but with gradually increasing recovery which was almost complete in the last sample. By this time grain from the first sample, which had been stored air-dry in the laboratory, had also matured. It is clear that the tendency of grain to sprout during harvest will depend not only on the atmospheric conditions but also on its state of dormancy. When hot dry weather, which will hasten maturation, is followed by rain, conditions are most favourable for sprouting, in a cold damp season grain is likely to show less tendency to sprout in a rainy harvest. It must, however, be realized that if favourable conditions prevail for a sufficiently lengthy period, even very dormant grain will eventually germinate unless some external agency such as mould intervenes to make an end.

During the past harvest season, we have been able to carry out a preliminary investigation on the degree of resistance to sprouting exhibited by several varieties of wheat. By the kindness of Mr H. W. Gardner, Hertfordshire Agricultural Institute, we were able to examine samples of nine wheat varieties grown, with and without nitrogenous supplement, side by side on three different sites selected for

differences of soil condition. On the first of these sites the crop had been cut, stooked and carried in good weather and had escaped sprouting. On the other two, harvest conditions had been by no means so good, wet weather causing a degree of sprouting in several instances. Weight percentages of sprouted grain separated by the hand-picking of sub-samples weighing not less than 80 gm are set out in the following table.

Variety	Percentage sprouted grain			
	Site II		Site III	
	No nitrogen	Nitrogen added	No nitrogen	Nitrogen added
Holdfast	39.7	24.4	27.1	26.8
Steadfast	42.6	48.6	34.0	19.9
Julana	30.1	25.8	7.8	12.2
Squarehead's Master	18.1	16.7	4.1	1.6
Scandia	17.6	7.3	4.2	2.3
Weibull's Standard	3.8	8.4	1.0	1.2
Desprez 80	19.7	23.0	1.7*	0.5*
Vilmorm 27	2.9	0.9	4.1	6.1
Little Joss	6.1	6.4	2.6	4.0
Total average	20.05	17.95	9.6	8.3

* Desprez 80 from Site III was immature and thus very dormant, as with unripe grain after sun-drying. Results for Site II are probably a truer indication of the tendency of this variety to sprout.

These results indicate, as might be expected, that nitrogenous manuring has no substantial influence on the dormancy period of wheat, the small differences shown in the table being probably adventitious. On the other hand, as between varieties, Holdfast, Steadfast and Julana seem especially prone to sprout, a tendency accentuated on Site II where harvest conditions were even more severe than on Site III. Squarehead's Master seems to occupy an intermediate position, while Little Joss, Weibull's Standard and Vilmorm 27 appear to be much more resistant. This conclusion has been to some extent confirmed by the examination of isolated individual samples from other sources, which suggest that while soft white wheats such as Wilma and White Victor sprout readily, Als, Atle, Iron II, Redman, 60 and Bersée are resistant.

Further confirmation of some of our findings has been communicated privately to us by Dr Hunter, of the National Institute of Agricultural Botany, who has noted that during the harvest of 1944 sprouting trouble was especially prevalent in Holdfast, Steadfast and Julana.

It has to be admitted that our data are at present insufficient to decide as between varieties on their relative dormancy periods. It is hoped, however, to obtain such information during the next season. In considering the preliminary data, it has to be remembered that all varieties were reaped and carried at the same times, and hence the earlier ripening varieties have been exposed to a more severe test. As regards breadmaking quality, it is disconcerting to find that the majority of the resistant wheats are generally thought to be poor. On the other hand, it has recently been suggested by Johnston^{5,6}, and by Harrington and Knowles⁷ that dormancy may be an inherited character. If such be true, it should offer possibilities to the plant breeder, and in fact, in the case of barley, Freistedt⁸ has already directed attention to this.

The general problem would appear to be one of some importance if we continue to grow wheat in Britain for bread-making.

UNIVERSITY REFORM IN BRITAIN

By DR. RAYMOND PRIESTLEY

Vice-Chancellor, University of Birmingham

UNIVERSITY reform is in the air to-day. The amount of discussion about the future of higher education that is going on among thinking people—and to-day a greater proportion of citizens are thinking than usual—cannot but do good. Isolationism—the 'ivory tower' conception of the role of the university—has always been liable to become a limiting factor in its usefulness.

The National Union of Students has recently discussed the subject, and has issued a report*, the chief characteristic of which is its entire reasonableness. One somehow expects student opinion to run to extremes, usually to the Left. It would indeed be unnatural if youth were satisfied with the present condition of affairs. But all the suggestions put forward here are in my own opinion worthy of thoughtful consideration by university authorities.

Here, as elsewhere, the abolition of fees tends to become a fetish or King Charles' Head. Education for all who are worthy to the limit of their need and powers is a first-rate end, but I do not believe that, in our present state of society, abolition of fees is the best means to that end. Nor is it likely to be for some time. There are very many people to-day who can afford to pay for their university career. Many find pride in doing so. Unless we drastically change our methods of selection—getting away from the purely intellectual sieve—we should, if we exclude fee-paying students, lose a valuable element of student life. Oxford and Cambridge in particular have benefited from the leavening influence of many men who would not have reached a university on intellectual qualifications alone, and no one has benefited more from their presence than the scholars themselves.

Also, while our society is so constituted that men exercise influence more than the average through accident of birth and wealth, it is good that they should, as part of their education, live in a university atmosphere for some years. Again, government is not yet so conditioned that the universities would not be financially crippled if fees were eliminated from their income. First we need the Government and local authority grants doubled and doubled again. I am therefore against the abolition of university fees. The time is not nearly ripe. What would be the value of flooding impoverished universities with students for whom we cannot cater properly, while excluding men and women all of whom to-day have to prove their intellectual fitness for university education through entrance examination, many of whom select themselves on other grounds better than some scholars, and most of whom, as society is organized to-day, are going to play an important part, and should have the best possible preparation. The abolition of fees in universities might be a proper and necessary feature of a social revolution, but as an incident of university organization to-day it is premature and out of place. Let us, on the other hand, have more generous maintenance allowances and more scholarships. Most of our anticipated expansion in numbers should derive from that source.

The need for, and value of, a high standard of character and personality as well as intellect in university personnel—be they staff or students—make the more important one recommendation that I can heartily endorse: compulsory residence for one year at least. I would go further and ask for two as a minimum. It is a debatable point whether, if only one is required, the freshman year is the best. Different colleges at Oxford and Cambridge hold different views about this.

An interesting point raised is the question of student representation on university governing bodies. At the University of Birmingham students are represented on the Court. This is a good thing, but it means very little in practice. At the University of Melbourne they are represented on the Council. That was never an embarrassment to the University during my tenure of the vice-chancellorship, and I do not believe it had been before. What the National Union of Students means by direct access to council, senate and faculties is not clear, but I do not believe any such body would refuse to see a deputation of students if asked, certainly not in any university on the staff of which I have served. I agree, however, with the Union that the most promising method of integration is through staff-student committees. I think few heads of departments, if properly approached, would refuse to participate in such discussion groups. A good example of this sort of co-operation is the Arts Council at the University of Birmingham.

The revolt against over-lecturing is natural, but can, I think, be overdone. Spoon-feeding would be as bad as under-nourishment. Let us have more seminars and informal tuition by all means. I have tried out the cyclostyled notes idea, and on the whole it was not a success. It was useful occasionally for broadcasting diagrams or charts, or especially difficult arguments, but used as a general rule it made for slackness and inattention, at least in some subjects and with certain types of students. I can imagine, however, that the issue of regular notes might be valuable in certain subjects. Personally, I would rather have students stay away and read than be compelled to attend lectures in which they are not interested. In this, as in many other things, however, a vice-chancellor carries less weight than professors, and he must defer to their specialist knowledge of teaching.

For the rest, a vigorous student union, as autonomously governed as possible, is an essential requisite for satisfactory life in the non-residential university. The sad thing to-day is the fact that the educative influence of the union is confined to a minority of students. The majority use the building only as a restaurant, lounge and dance hall. Only student opinion and student influence can remedy this. Many never go near the union at all. They are the 'brown baggers' of whom we hear so much. The only answer to them is compulsory residence in halls of residence generously equipped with a staff whose interests are student-centred, and with the amenities that foster community spirit and social activity.

I would agree with the estimate that student numbers in British universities should be increased over all by 50 per cent, though, since Oxford and Cambridge are near saturation point, this will mean doubling the size or number of the provincial universities. The remarks made about the curriculum are well worth study by university senates, which are, indeed, not unaware of the need for reform.

* The Future of University and Higher Education: a Report prepared by the National Union of Students of the Universities and Colleges of England and Wales. Pp 16 (3 Endsleigh Street, London, W C1, 1945) 6d.

Many faculties are vigorously discussing these questions now

Nearly all the proposals in what is a useful and provocative little booklet mean greater expenditure. We must hope that those who hold the purse-strings will realize that to-day the universities are a long way behind scratch. The greater part of the first increases of grant will be expended in bringing us back into line for a good start after the backsliding made inevitable by six years of war.

It has been difficult to review the report issued by the National Union of Students in a short article—it is quite impossible to do justice to the many subjects touched upon at the Second Educational Conference of the Association of Allied Professors and Lecturers, held in London on April 14, 1944, the proceedings of which are now available*. Mental indigestion and a seething mind are inescapable after a first reading. There are, however, some impressions that pick themselves out. The modern Soviet university seems to have got farthest from the 'ivory tower' idea, but this has been incidental to profound social and political changes. Unless we are prepared to follow them in the larger field—and I for one think that we should lose more than we should gain by doing so—we must seek to attain the same end by more devious ways. The United States are trying hard to achieve an educated democracy and have had a measure of success. It has been easier in a country with an expanding frontier than it has been in overcrowded Western Europe with its bounds set by history and tradition. It will be less easy in the America of the future, when the expanding frontier will be a memory of the past. When I visited the United States in 1936, the Federal Government was spending sixty million dollars a year on student maintenance, because it was becoming progressively more difficult to work one's way through college in competition with the regular labour force.

I like Sir Fred Clarke's definition of training as "the cutting edge that makes education specifically

serviceable". General acceptance might give the word and idea a new lease of respectable and useful life. Interchange on the Franconi chair scale, with its fully equipped laboratory and specialist assistants for the visiting professor, approaches the ideal, and is linked in my mind with the good idea of occasional interchange between the professor and master of the school sixth form. The greatest professors like taking elementary classes despite what Bruce Truscott says. It is not too great a step to go back to school, though the step would certainly be new. The American system of sabbatical leave and the junior's *wanderyahr* have done much for peaceful penetration into China, and the British Commonwealth might well emulate their trans-Atlantic cousins here. Of the great university dangers, 'specialization, mechanization of learning, and interference by the State', we in Britain know something of the first two, but we have steered clear of the third thanks to our genius for anomalies in our government set-up. Long may that remain true.

Sir Ernest Barker has likened the ancient universities to mountains of ice nine-tenths submerged in seas of history and tradition. Having had experience of Antarctic exploration, I am tempted to carry the analogy a step further. The new universities are more like the snowbergs from the Antarctic continent with half their bulk above water. They may have a more workmanlike façade, if a different one. They are without the peaks and pinnacles, but there is something to be said for a solid rectangular shape. They are more responsive to the winds of public opinion. They are more readily adaptable to the social environment in which they are set. These are, on balance, not bad characteristics. I will not press the analogy too far, for icebergs and snowbergs alike, when they grow older, pass through the stage of being hidden dangers to navigation; and finally they disappear leaving no trace.

NEW FELLOWS OF THE ROYAL SOCIETY

The following were elected fellows of the Royal Society on March 14.

MR L. COLEBROOK, a member of the scientific staff of the Medical Research Council. Distinguished in the application of bacteriology to clinical medicine, he played a leading part in the practical establishment of the 'sulpha' drugs, and has thrown much light on the fevers of childbirth. During the War he has directed important investigations on burns.

MR W. S. FARREN, aeronautical engineer, director of the Royal Aircraft Establishment, Farnborough. He has been associated with aeronautical research and development continuously since 1914, and has contributed greatly to advances in the science and practice of aeronautics.

DR N. FEATHER, lecturer in physics in the University of Cambridge, distinguished for investigations which have added much to knowledge of the spontaneous and induced disintegrations of atomic nuclei.

PROF J. H. GADDUM, professor of pharmacology in the University of Edinburgh, distinguished for his work on the identification and estimation of acetyl-

choline, adrenaline and histamine in animal tissues and for his experimental contributions to the conception of cholinergic and adrenergic nerves.

DR H. GODWIN, lecturer in botany in the University of Cambridge, distinguished as a plant ecologist, and especially for his contributions to the knowledge of the post-glacial history of British vegetation based on the pollen analysis of recent deposits.

PROF J. M. GULLAND, Sir Jesse Boot professor of chemistry, University College, Nottingham, distinguished for his analytical and synthetic work in the phenanthrene group of alkaloids, and for his work in the development of the chemistry of substances of biological importance.

MR H. W. HARVEY, marine biologist, distinguished for his contributions to our knowledge of the 'productivity of the sea' by co-ordinating the varied factors, physical, chemical and biological, which determine it.

PROF V. C. ILLING, professor of oil technology in the Imperial College of Science and Technology, distinguished for his researches on the relation of texture of sediments to oil accumulation, and for

refinements of stratigraphical and geophysical methods applied to interpret the structure of oil-bearing lands.

MR A E INGHAM, University lecturer in mathematics in the University of Cambridge, distinguished for his researches in pure mathematics, particularly in the theory of numbers

PROF H D KAY, director of the National Institute for Research in Dairying, distinguished for his biochemical work, particularly for his investigations upon organic phosphorus compounds and the phosphatases. Recently he has applied his methods to the practical problems of dairying

DR. W B LEWIS, lecturer in physics in the University of Cambridge, distinguished both for his contributions to the investigation of the structure of atomic nuclei and also to the development of the science of electronics, with special relation to ultra-high frequency radiation.

DR KATHLEEN LONSDALE, physicist, Royal Institution, distinguished for outstanding contributions to the investigation of the crystalline structure of organic compounds by means of X-ray analysis. Particularly important have been her recent researches into the fundamental mechanics of crystal structure.

PROF P C MAHALANOBIS, professor of physics, Presidency College, Calcutta, and founder of the Statistical Laboratory, Calcutta; distinguished for his contributions both to statistical theory and to the applications of statistics, particularly to sample surveys, agriculture and population

PROF R E PEIERLS, professor of applied mathematics in the University of Birmingham, distinguished for his contributions to theoretical physics, particularly in the application of quantum mechanics to the electron theory of metals and other phenomena of the solid state, and in the theory of the atomic nucleus.

PROF J MONTEATH ROBERTSON, Gardiner professor of chemistry in the University of Glasgow, distinguished for his work on crystal structure by the methods of X-ray analysis. He has made measurements of great accuracy in this field, and has derived from them precise molecular structures, electron density distributions, and inter-atomic distances of organic molecules

PROF F M ROWE, professor of colour chemistry and dyeing in the University of Leeds. As leading dyestuff technologist, his work has been of national importance. He has made varied and original contributions to the chemistry of dyes and intermediates.

SIR WILLIAM WRIGHT SMITH, King's botanist in Scotland, regius keeper of the Royal Botanic Garden, Edinburgh, and regius keeper of botany in the University of Edinburgh, distinguished for his contributions to the taxonomy of Angiosperms, and especially for his monographic treatment of the genera *Primula* and *Rhododendron*.

MARJORY STEPHENSON, a member of the scientific staff of the Medical Research Council, distinguished for her biochemical researches upon the metabolism of bacteria, which, with those of her pupils during twenty-five years, have included work upon hydrogenase, lactic dehydrogenase and adaptive enzymes

MR B N. WALLIS, mechanical engineer, chief of research and development of Vickers-Armstrong Ltd, Aircraft Section. He has been responsible for many new projects of design, and his work has led to secret developments which have been of great importance in the war effort

MR. J. Z. YOUNG, lecturer in zoology in the University of Oxford, distinguished for his outstanding contributions to knowledge of the nerve fibre, both of its structure and function. During the War he has worked on important clinical aspects of the repair of damaged nerves

NEWS and VIEWS

Prof. Guido Castelnuovo

MATHEMATICIANS will be pleased to learn that Prof Guido Castelnuovo, formerly professor of geometry in the University of Rome, is safe and well. In a recent letter to Mr L Roth, of the Imperial College of Science and Technology, London, he relates that he, with members of his family, obtained refuge during the German occupation of Rome, and that he has now returned to his well-known house in the Via Boncompagni. Castelnuovo is eighty years old this year; the world of science will unite in congratulation. Castelnuovo's work (which was reviewed in *Nature* of December 10, 1938, p 1016) represents the best in Italian geometrical thought over a long period. Born in an age which, to quote his own phrase, "closed one epoch and opened another", his first papers were, naturally enough, on the projective geometry of higher space. But soon, with Corrado Segre, he was making essential contributions to the algebraic geometry of curves which, sixty years ago, was beginning to assume its modern form. Then, in 1894, with Federico Enriques as his collaborator, he initiated the study of the algebraic geometry of surfaces, on no firmer a foundation than the hints and conjectures (some of them mistaken) of Max Noether. Much of this work is definitive, in a negative as well

as in a positive sense, for where he has paused, his successors in the field have often found it impossible to progress. Perhaps the most celebrated of Castelnuovo's papers is the memoir of 1896, in which he gives necessary and sufficient conditions for the rationality of a surface, that is, for the existence of a one-to-one algebraic correspondence between the points of the surface and those of a plane. Incidentally, this was quite literally a piece of research, in that the author did not suspect what the conditions were before he began to write the paper. So the theory of rational surfaces was able to take its place by the side of the classical theory of rational curves.

Already (and, in fact, during the previous ten years), Italian geometers were posing similar questions for the threefold, that is, the locus which is represented analytically by an equation in four co-ordinates. The quadric threefold, like the quadric surface, is easily seen to be rational by projecting the locus from a point of itself. It was also well known (though the proof is less obvious) that the general cubic surface is rational. The question now arose, what could be said about the general cubic threefold? The question was destined to become one of the historic problems of geometry. At first glance one could see that the answer would either be imme-

diate or else very difficult to obtain. A first attempt fell wide of the mark. Segre, in his great work on cubic threefolds, written about 1887, had tried to grapple with the problem, but it turned out that the varieties he considered, though rational, were not general of their type. The problem was then taken up by Prof Gino Fano, of Turin, one of Castelnuovo's first pupils. In a struggle which has lasted some fifty years, Fano has made vital contributions to the subject, culminating last year with the news, in a letter from Switzerland, that he had succeeded in showing that the general cubic threefold is irrational. It would be an under-statement to say that geometers await with impatience the appearance of Fano's investigation.

Miss P. M. Taylor

MISS P. M. TAYLOR, who has recently been appointed woman educational officer to the Central Council for Health Education, was educated at Girton College, Cambridge, and Westfield College, London. Miss Taylor joined the executive committee of the Association of Women Science Teachers in 1932, and in 1935 was elected honorary general secretary, in which capacity she served until October 1944. Her new position with the Central Council is an important one which necessitated her relinquishing the onerous duties of the general secretaryship of the A S W T, though she was re-elected to the Executive Committee this year. The present investigations of the Association, which have already resulted in the publication of the pamphlet "Pre-Nursing Course in Schools" (1943) and the Interim Report on Science in Post-Primary Education (1944), are in a large measure due to the initiative and exceptional powers of organization of Miss Taylor. The Association is fortunate in having her continued co-operation in the completion of this work, the results of which it is hoped to publish shortly. Miss Taylor's zeal is unabated, in spite of the calls made upon her and her capable assistants during the war years to keep in touch with the members. Their success is seen in the vigorous growth in membership and the widespread interest in progressive methods of science teaching, which factors have necessitated the appointment of a full-time secretary. In addition to her work as honorary general secretary, Miss Taylor has served on the Education Advisory Committee of the Central Council for Health Education, the Consultative Committee to the Nursing Reconstruction Committee, Royal College of Nursing, and as president of the Essex Branch of the A S W T. She held the post of senior science mistress at the Southend-on-Sea High School for Girls until July 1944.

Agricultural Zoology in Scotland

DR D. S. MACLAGAN, lecturer in zoology at King's College, University of Durham, has been appointed head of the Department of Zoology of the West of Scotland College of Agriculture, Glasgow, and research advisory officer in agricultural zoology for the south-west of Scotland, in succession to Prof L. A. L. King, who has retired. Dr MacLagan held a Ministry of Agriculture research scholarship during which he carried out work at the Parasite Laboratory of the Imperial Bureau of Entomology and at Harvard University, and later worked with a Carnegie research fellowship at the University of Edinburgh. He is known for his work in animal ecology and on the dynamics of animal populations.

Cosmic Ray Investigations in Armenia

THE preliminary results of the Alagez Expedition of 1944 for the study of cosmic rays have been published in the U S S R. Observations have been made each year since 1942 from a camp on Mt Alagez in Armenia at a height of about 10,000 ft above sea-level. All instruments, supplies and camp equipment had to be carried on pack animals. As conditions are extremely favourable for the study of cosmic rays, it has now been decided to build a permanent station there, with an observation post at about 13,000 ft. It is now believed that cosmic rays contain a third element in addition to mesotrons and electrons. The particles which make up this third element have a greater ionizing effect on air than either mesotrons or electrons. The latest expedition spent three months in attempting to discover the nature of this third component, especially the mass of the particles of which it is composed. The difficulty was to separate them from the other already known components. New methods were evolved, and some new and extremely sensitive instruments built. The particles were found to have properties very similar to those of protons. The part they play is apparently more significant than was at first realized. Only preliminary data, however, have been obtained, and the material is still being studied. The expedition made several thousand observations during great cosmic ray showers for the purpose of determining the energy of the cosmic particles which cause the showers. It was found to be enormous. A special kind of shower, occurring over a very small area, but including a tremendous number of particles, was also discovered.

Stone Age Implements in India

INDIA is rich in relics of Stone Age man, and the prehistorian there has a wide field for research. Not a great deal of new information will be gleaned from "Pre- and Proto-history of Gujarat" (H. D. Sankalia, reprinted from "The Glory that was Gūrjaradesa", 1943), though the gazetteer of finds at the end of the article is useful so far as it goes. What the prehistorian asks from researchers in the field in India is definite stratigraphical data. Perhaps, therefore, the geological section of the right bank of the Sabarmati River at Pedhāmli appearing on p. 15 is the most important single item in the article. It would seem that, as throughout Madras, early Stone Age artefacts come from a gravel conglomerate which rests immediately upon laterite. The occurrence of a microlithic industry suggests that its makers were using composite tools in which several 'pigmy' flints were hafted together to form one efficient instrument. Such industries appear at various different periods when natural circumstances permit or encourage their development and may be of widely different ages, and one must enter a caveat against the wisdom of trying to correlate the microlithic finds of Gujarat with those of Europe. In India itself, Colonel Gordon, in "Indian Art and Letters" (1936), has shown that the rock-shelter paintings in the Mahadeo Hills are not very old—maybe first century B.C. to tenth century A.D. in date. There the only industries found in the rock-shelters below the paintings consist of typical Indian pigmy artefacts. Near the surface a little pottery occurs, in lower levels this is absent. The conclusion would seem to be that the pigmy industries themselves are not very old and certainly nothing to do with the European Mesolithic either culturally or in time. This is also true of the numerous

microlithic industries in quartz found in Ceylon. Dr Sankalia ("The Second Gujarat Prehistoric Expedition A Preliminary Account of the Search of 'Microlithic Man in Gujarat,'" by H D Sankalia and I Karve, *New Indian Antiquity*, 7, No 1, April 1944) has described the unearthing of some skeletons, believed to belong to the folk who made the pigmy objects described. Physical anthropologists will naturally await with interest a complete account of these finds when the final study of them has been made.

Community Centres

THE report on community centres recently prepared by the Ministry of Education (Pp 40 London H M Stationery Office 9d net) is a document of much importance. The Government has decided that the provision of such centres to promote the social and physical training and recreation of the community should be regarded as coming within the scope of the education service administered by local education authorities, such provision being covered by Section 53 of the Education Act, 1944, without prejudice to the power of other local education authorities under Section 4 of the Physical Training and Recreation Act, 1937, to provide centres for athletic, social or educational objects. Arising out of that decision, this report has been prepared at the instance of the Minister of Education by some of his officers, and is now published for general information. The first chapter of the report goes at once to the root of the matter. "During the present century, the day-to-day life of the British people has been profoundly affected by two parallel and closely related developments—the mechanisation of industry and a progressive reduction in working hours. The reduction in working hours may have been largely due to the growing demand for more leisure, but it was mechanisation which made it possible to meet the demand". That is the point of departure taken in this searching and comprehensive report, that, and another fact plain to be seen, that it is one thing to have spare time and another to know how to use it wisely. Though the report does not expressly say so, it means that we have reached a position in which the twofold distinction between work and leisure should be replaced by a threefold distinction between (1) work, done for a living, whether one likes it or not, (2) relaxation, play, recreation, for the recovery of poise, and (3) true leisure, spent upon pursuits which may make it in one way or another "the growing time of the spirit". In subsequent chapters the report goes into detail about the organization, staffing, provision and maintenance, and ownership, control and management of community centres. A valuable appendix sets forth the suggested accommodation required for neighbourhood units in varying situations.

Control of Rabies

In an interesting leading article, the *Lancet* (628, Nov 11, 1944) directed attention to the need for the existing regulations designed to prevent the reintroduction of rabies into Great Britain. The law requires that all dogs imported, by air or otherwise, shall be quarantined for six months; strict insistence on this regulation would prevent the reappearance in Britain of this serious disease. Rabies is primarily a disease of dogs, cats and allied species, but it is communicable to man and to domesticated animals by the bite of a 'mad' dog. It was first recorded in Great Britain in

A.D. 1000, but it probably existed here before that date. In the middle of the eighteenth century it raged among dogs in London and elsewhere. In the nineteenth century it broke out among several packs of fox-hounds, and some thirty-six persons a year died of rabies. By 1902 rabies had been eradicated from Great Britain by stringent control measures, and it did not reappear for sixteen years. By then (see Stockman, S, *Vet Record*, 32, 135, 1929, quoted by the *Lancet*, loc cit) the public was so unfamiliar with the disease that some sections of it failed to realize the dangers of its reintroduction, and the abnormal conditions of that time doubtless helped its spread.

Rabies was found among dogs in Great Britain in September 1918, the infection having been brought in by smuggling dogs into the country by air. The Ministry of Agriculture took energetic measures against it, and these measures were helped by the fact that most of the dogs were affected by the dumb or paralytic form of the disease, which greatly restricts their wanderings and ability to bite, and also by the fact that the disease broke out in Cornwall, which is isolated to some extent from the rest of England, most of the affected dogs wandered west to the sea. Nevertheless, some seventeen counties became involved, 327 dogs died of the disease and 368 human beings were bitten and had to be treated. The outbreak was not controlled until December 1921 (see *Lancet*, 11, 719, 1926). In the United States, during the last ten years, there has been an average of fifty-seven cases a year, and some States have recorded more than a thousand cases a year among animals. Rabies vaccines are available, and the *Lancet* (628, Nov 11, 1944) discusses the value of these, which has been questioned. Meanwhile it cannot be too widely known that rabies will, if it comes again to Great Britain, cause much suffering among men and animals. The quarantine regulations, which can keep rabies out of the country, should therefore be vigorously supported.

Stars or Planets?

PETER VAN DE KAMP has an article with this title in *Sky and Telescope* of December 1944, in which he deals with the question of the criterion for stars and planets—a matter of considerable importance in view of the fact that recent discoveries have shown the existence of 'planets' fifteen or twenty times the mass of Jupiter. He accepts Russell's critical value of 1/20 of the sun's mass as a conventional borderline between visible stars and the invisible bodies which can be designated as 'planets'. This criterion defines a planet or star, therefore, by its mass, not by its size. Among the methods for detecting unseen companions of low mass is the photographic method applied to nearby stars, and if the determination of the orientation of the perturbation orbit were sufficiently accurate, good results would be obtained. Difficulties arise from the fact that photographic star images are 1"-3" in diameter, and most of the recently discovered perturbations have a total amplitude of less than 0.1". The gravitational method for discovering faint companions of low mass, while it is more powerful than the direct visual approach, has decided limitations for very low masses, and it would be extremely difficult by this method to find companion masses less than 1/100 times the sun's mass, even for the nearest stars. The star which seems unattended by dark companions may be the exception, and it is possible that the stars attended by massive companions, rather than by small planets,

are in the decided majority. Our solar system may prove to be an extreme type of system, rather than an average type. Though generously endowed with planets, the sun is the only star known that has no close companion star.

Optical Phenomena in the Atmosphere

L/CPL V S TAYLOR, 6 Field Park Coy., R.E., C.M.F., writes "The discussion on optical phenomena in the atmosphere in *Nature* of December 9, 1944, brings to mind an occurrence frequently witnessed at Anzio while it was a beachhead. During, and immediately after, intense A.A. fire under conditions of virtually clear sky, with the sun behind the observer, concentrically disposed wave ripple arcs could be seen passing away from the barrage zone, in the portion of the sky about 45° forward of the observer. The acute compression of the atmosphere peripheral to the bursting shells caused the compression zones to be sufficiently altered in refractive index to produce an optically visible phenomenon when refracting undiffused sunlight." This phenomenon would seem to be similar to the concentric waves observed by Dr A. H. Goldie following a bomb burst (*Nature*, 154, 738, 1944).

Post-War Bread in Britain

THE Ministry of Food, in collaboration with the Health and other Departments interested, has arranged a conference with the industrial and trade organizations principally concerned with post-war bread. It is hoped that the discussions of the conference will assist the Departments in advising Ministers on post-war flour and bread policy and in particular on any regulations which may have to be made after war-time control ends. The milling and baking industries, the flour importing trade and the co-operative movement have been asked to nominate representatives to the conference, invitations will be addressed to other interests later as may be necessary. The conference will be attended by the Lord Horder (personal adviser to the Minister of Food on medical aspects of food problems), Sir Jack Drummond (scientific adviser to the Ministry of Food), Sir Wilson Jameson (chief medical officer of the Ministry of Health), Dr Andrew Davidson (chief medical officer for the Department of Health for Scotland) and Sir Edward Mellanby (secretary of the Medical Research Council). In addition, there will be present administrative officers representing the Ministry of Food, the Ministry of Agriculture and Fisheries and the Ministry of Health. Sir Henry French, the permanent secretary of the Ministry of Food, will be the chairman of the conference.

Agricultural Scholarships

THE Ministry of Agriculture and Fisheries invites applications for ten senior scholarships, tenable at university departments of agriculture, or agricultural colleges, for degree or diploma courses in an agricultural subject, or at veterinary colleges for courses in veterinary science, and for six extended junior scholarships (for those who have already held junior awards), and sixty junior scholarships, tenable at farm institutes or similar institutions, for courses not exceeding a year, in agriculture, horticulture, dairying or poultry husbandry. The scholarships are open to the sons and daughters of agricultural workmen or of working bailiffs, smallholders and other rural workers, and to persons who are themselves *bona fide* workers in agriculture. The value of the awards

is such that neither the recipients nor their parents are normally required to make any contribution towards the cost of the training provided. The usual method of selection is by interview. Full information concerning the scheme and forms of application may be obtained from the Secretary of the Ministry, Block 4, Bickenhall Mansions, Baker Street, London, W 1, or from the offices of County Councils. The latest date for submitting applications is April 30, 1945.

The Night Sky in April

NEW moon occurs on April 12d 12h 29m U.T., and full moon on April 27d 10h 33m. The following conjunctions with the moon take place: April 9d 19h, Mars 3° N., April 17d 13h, Saturn 0 1° N., April 23d 06h, Jupiter 3° S., April 26d 18h, Mercury 6 3° S. Only one occultation of a star brighter than magnitude 6 takes place in April, namely, 8 Leon, which disappears on April 21d 1h 29 7m. Mercury sets at 20h 11m at the beginning of April and rises at 4h 10m at the end of the month, about 25 minutes before sunrise. The planet is in inferior conjunction on April 13 and is stationary on April 3 and 25. Venus is a conspicuous object in the western sky in the early portion of the month, setting at 21h. on April 1. On April 30 the planet rises at 3h 35m, an hour before sunrise. Venus is in inferior conjunction on April 15. Jupiter is visible throughout most of the night, setting at 5h 13m and 3h 14m at the beginning and end of the month, respectively. Saturn can be seen in the early portion of the night, setting at 1h 49m and just after midnight at the beginning and end of the month, respectively. The Lyrid meteors are active during April 18-22, but moonlight will interfere with the observation of the shower.

Announcements

WE regret to record the death on March 23 of Sir Napier Shaw, F.R.S., the doyen of British meteorologists, aged ninety-one.

BOTANISTS will be pleased to learn that Mr E. J. H. Corner, assistant director of the Botanical Gardens, Singapore, who has been in the hands of the Japanese since the fall of Malaya is, according to a cable received from him, "well, happy, working as a botanist."

DR THOMAS A. JAGGAR, the well-known volcanologist, has been awarded the Franklin L. Burr Prize of 1,000 dollars by the National Geographic Society. The Prize, established under a bequest of the late Mary C. Burr of Hartford, Connecticut, provides for cash prizes to members of the Society's expeditions considered to have done especially meritorious work in the field of geographical science. The award was made to Dr Jaggar for his part in the development of an amphibian mobile boat in 1927, which was used by a National Geographic Society expedition headed by Dr Jaggar to carry on researches in Alaska in the region of Pavlov Volcano during 1927-28.

A COURSE of twelve lectures in special librarianship has been arranged by the Association of Special Libraries and Information Bureaux, and will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, at weekly intervals starting on April 18, at 4.30 p.m. Applications to attend should be sent to the General Secretary, ASLIB, 52 Bloomsbury Street, W.C.1, as soon as possible, the fee is £5 5s. for the course.

✓ Age of the South African Ape-men

THE determination of the age of mammalian fossils of the later Tertiaries is a matter of the greatest difficulty. In America, Pliocene land beds are rather rare, and except in Europe where we can divide the Pleistocene by its Ice Ages, the classification of the Pleistocene is also very difficult. We have had many different views of the ages of the Siwalik deposits by Falconer, Lydekker, Pilgrim and Matthew. In South Africa we are in much greater difficulty as the majority of our mammalian fossils are not nearly related to those of Europe or Asia, and are even less related to those of America.

The determination of the age of the caves which have yielded the skulls and remains of the Australopithecines or ape-men is a matter of very great importance, as these Primate fossils show remarkable affinities to man. If they are Pleistocene they were contemporaries of man, though probably survivors from a family from which man arose in the Pliocene. If they are Pliocene they may be nearly related to the ancestor of man, and *Australopithecus* — the Taungs ape-man — may be so near to ancestral man as to be practically the 'missing link'.

At Kromdraai true horse (*Equus*) teeth are abundant. There is a large horse and a small one, so we may consider the Kromdraai ape-man *Paranthropus* as belonging to some part of the Pleistocene.

The Sterkfontein ape-man *Plesianthropus* is certainly of a very different age. No species of mammal is known from both Sterkfontein and Kromdraai except perhaps two species of the rats of the genera *Mystromys* and *Otomys*. The 'baboons' are different, the jackals are different, and so are the dassies. Further, no horse teeth are known from the Sterkfontein cave, though they have been found only 150 yards away. As a porcupine occurs which does not seem to differ from the living species, I thought it safer to keep *Plesianthropus* in the Pleistocene, though the presence in the cave of two species of sabre-tooth cats seemed to point to the deposit being old; but there was always the possibility of sabre-tooths surviving into Pleistocene in South Africa after they had died out in Europe and Asia.

The Taungs ape is manifestly much older than those others. The associated fauna is quite unlike that at Sterkfontein or Kromdraai. I, therefore, provisionally placed the Sterkfontein and the Kromdraai ape-men in Middle Pleistocene, and the Taungs ape-man in Lower Pleistocene, though not improbably belonging to Upper Pliocene.

I have just had given me a few days ago by the

Abbé Breuil the snout of a primitive hyæna. This was found by Dr H. K. Silberberg at Sterkfontein three years ago. I have seen Dr Silberberg and find that he picked up the specimen in the lower part of the Sterkfontein cave. The spot is almost directly below that in which the *Plesianthropus* type skull was found, but at about 60 ft lower level. The fossils which I have collected at this lower level appear to be similar to those above.

We already knew a species of *Crocota* from Kromdraai very closely allied to the European *Crocota spelæa*, and from some part of Sterkfontein a jaw of *Hyæna hyæna*, and from the main Sterkfontein cave portions of a hyæna with the crowns of the teeth hopelessly broken. The hyæna discovered by Dr. Silberberg is a Pliocene type which must, I think, be placed in the genus *Lycyæna*. *Lycyæna* is a primitive genus found in the Lower and Middle Pliocene of Europe and India. While there is a possibility of the Pliocene *Hyæna* surviving into Pleistocene with the sabre-tooth cats, it now seems more likely that the Sterkfontein cave is Pliocene,

DENTITION OF *Lycyæna' silberbergi* BROOM. NAT SIZE

and if so we must put the other caves to an earlier date also.

The Kromdraai skull we may put as probably Lower Pleistocene, and the Sterkfontein as probably Upper Pliocene. The Taungs skull, which must be much older, we may assign to the Lower part of the Upper Pliocene or even to Middle Pliocene. Of course, it will be readily understood that the difficulties are great, and the evidence very little. The director of the South African Geological Survey, Dr A W Rogers, said in 1925 that "there was no probability of the age of the (Taungs) deposit being determined", and so far as I know no geologist has ever made any attempt to solve the difficulty. Still, some attempt must be made. So much hangs on it.

If the Taungs ape-man is of Pliocene, and possibly even Middle Pliocene, age it may again assert its claim to be very near to man's ancestor. Its teeth are practically identical with those of some Bushmen.

A full account of all we know of the South African ape-men has been prepared by Dr G W H Schepers and myself, and it is hoped that this work will be published this year

Transvaal Museum,
Pretoria

Index of Diversity as Applied to Ecological Problems

IN Research Items in *Nature* of December 30, p 833, attention is directed to Dr C B Williams' recent paper¹ in which he applies the 'index of diversity' (α) to populations of various kinds. He claims that α is a property of the population, and is independent of sample size. He attempts to use it for the relation between numbers of species and size of sample in samples of plant populations obtained by means of quadrats, and in using some figures of Gleason's implies that, given a random distribution of quadrats, the application of α would be valid.

It is difficult to test these assumptions directly, since it is usually impossible to count individuals of plants, and therefore impossible to obtain the relation between numbers of species and numbers of individuals. Recently, while engaged on work for the Forestry Commission, I obtained figures for the composition of various kinds of heath vegetation, using quadrats of different sizes. The figures obtained show that the index of diversity varied both with the way in which the quadrats were distributed (random or otherwise) and with the quadrat size. Thus α obtained by using quadrats of 1/8 square metre (quadrats being grouped together to give the varying sample sizes) was about 7, while α derived from counts of the mean numbers of species in quadrats of three different sizes (1/20, 1/8 and 1 square metre) was about 1.2. In the case of a piece of old *Calluna* heath in which there were only six species of flowering plant, 76 per cent of the cover being provided by *Calluna*, while *Empetrum nigrum* and *Vaccinium myrtillus* formed the remainder, the calculated number of individuals expected from Williams' formula was 3,000 per square metre. The actual number was not recorded, but the calculated number is obviously absurd.

Thus the index of diversity is apparently not applicable to numbers of plant species present in quadrats. The reason would seem to be that the formula takes no account of the amount of space occupied by the individual. In the insect populations first studied by Williams, sample size was defined by number of individuals—a fundamentally different method of sampling from that of taking quadrats, in which sample size is defined by area. The method of sampling an insect population comparable to taking a quadrat would be to take all the insects present in a given volume of space at any instant. While Williams' formula and the index of diversity derived from it may be valuable in some cases, it appears that the theoretical basis of its application needs further study.

E W JONES

Imperial Forestry Institute,
Oxford

I HAVE read with interest Mr Jones's letter on the results of the application of the logarithmic series and the index of diversity to his quadrat observations. I completely agree with him that the theoretical basis requires further study, as also does the field application to both animals and plants. The object of my publication, which gave a few cases selected over a wide field, was to stimulate the production of new data whether in support of the theory or not.

The essential difference between sampling in insects based on numbers and in plants based on area was emphasized by me both in the paper quoted and in an article in *Nature*¹. The application to botanical problems of a theory based on numbers of individuals was justified on the assumption that within one ecological formation the number of individuals could usually be considered as proportional to the area. This is only true if the size of the area sampled is large enough to contain a fair sample of the vegetation. In spite of this difficulty, I was surprised to find that in the sets of data that I collected almost at random from botanical literature, the results were consistent with the logarithmic series, and gave not unreasonable estimates of the numbers of individuals on a quadrat. If Mr Jones's figures do not so fit, then it will be interesting to find the reason.

Even in animals, however, it is not always necessary to know the exact number of individuals in order to apply many of the general principles of the log series, including the index of diversity. For example, if two random samples of insects from the same population by the same method give x individuals of 40 species and $3x$ individuals of 60 species, then it is

possible to say that $\alpha = \frac{60-40}{\log_e 3} = 18.2$, without know-

ing the value of x , except that it must not be too small. This very closely resembles the case of two quadrats of size 1 and 3 units with an unknown number x of individuals on each unit area.

In the limits of a letter, Mr Jones cannot give all the essential data, but I will take first his statement about quadrats of 1/20, 1/8 and 1 square metre giving $\alpha = 1.2$. This would suggest, on the basis of the log-series, that if there were x species on 1/8 sq m there should be approximately $x - 1.1$ on 1/20 sq m and $x + 2.5$ on 1 sq m ($x - \alpha \log_e 2.5$, and $x + \alpha \log_e 8$). On the other hand, his data for several quadrats of 1/8 sq m on the same area giving $\alpha = 7$ would imply that if there were x species on 1/8 metre, there would be about $x + 14.5$ on $8 \times 1/8$ sq metres, in other words, that eight separated quadrats of 1/8 sq metre gave 12 species more than 1 sq metre in a block. I suggest that the obvious explanation is that there was a strong aggregation of plants of each species in groups. When this is occurring, there will be very great differences between single small quadrats both in number of species and number of individuals, and one would not expect conformity with the log series unless the size of the sample was considerably increased. It is pointed out in the paper quoted that the application of the log series to quadrats is only justified if the number of individuals in the quadrat is large compared with α . In the locality studied by Mr Jones it seems likely that an area of 1/20 m, with plants as large as *Calluna*, might easily contain only one or two individuals.

Whether or not the whole conception of the log series could be extended to allow for aggregation, that is, to include a measure of it, I do not know,

¹ *J. Ecol.*, 32, 1 (1944)

but it is an interesting possibility. For the moment, I think it is better to say that with extensive aggregation the size of the sample must be increased.

I trust that I have done justice to Mr Jones's remarks, without having access to his data.

Colour Vision of the Fovea Centralis

I HAVE read with great interest the letters of Drs Stiles, Thomson and Pirenne in *Nature* of February 10, in which among other things König's early work is mentioned. Some experiments to be described below indicate, I think, that the factors involved are more complicated than has previously been supposed. Mr Willmer is under the impression that it is only the fovea centralis that suffers from some form of dichromatism. I find, on the contrary, that it is a considerable area of the retina which is affected at times by this defect, all that has to be done to make the greater part of the retina appear dichromatic is sufficiently to reduce the visual angle of the test object.

When König investigated the colour vision of his fovea centralis, and found dichromatism there, he found he had to preserve very strict central fixation, since small deflexions of the eye axes caused the true colours of the test objects to be perceived. Mr Willmer¹ found a similar state of affairs. "If the eye is focused not on the centre of the circle (circular test object) directly but on the point A, about 4 cm. from the centre of the circle, then all the quadrants stand out in their true colours." Now, I do not find this, and neither does my observer, G W J. In our cases, if the test object is small enough to cause dichromatic vision on the fovea centralis, then it is also small enough to cause similar dichromatism on whatever part of the useful retina the image falls.

Clearly there is here a marked difference of observation. But there is another difference even more marked which must be alluded to. Mr Willmer used as his test object a circle 2 cm. in diameter, which was divided into quadrants. He found that the colours of these quadrants became modified when the test object was viewed with one eye from a distance of about 3 metres. I have myself used his test objects, which he very kindly placed at my disposal for the purpose, and I found that I required a much greater distance than 3 metres for dichromatism to show itself.

The test object I have been employing consists of a bright yellow square, the dye used being a saturated solution of picric acid in water. If the square had 1 cm. sides, the distance required to exhibit dichromatism, by the square becoming white, would be approximately 16 metres. It would seem from these facts that my fovea centralis is more 'resistant' to dichromatism than Mr Willmer's in the sense that the test object has to be reduced in size much more for me than it has for him.

Two of my observers, E C T and J E T, obtained substantially similar results to myself, on the other hand, two other observers, J L de S and G N J, approximate more to Mr Willmer in their experimental findings. It is clear that observers differ in detail, but in this important particular they are all alike: all find that dichromatism is

not a property of the fovea centralis alone, but is present also in the more peripheral parts of the retina. The following example brings out this point clearly.

The observer G W J found that his fovea centralis was trichromatic when the distance of the test object was 3 metres from his eye. It was dichromatic when the distance was 4 metres. The demarcation between the two types of vision occurred at about 3.6 metres. When a fixation point 4 cm. to one side of the test object was fixated, trichromatism was found at 3 metres, dichromatism at 4 metres, the transition between the two types of vision occurring at 3.3 metres. When the fixation point was 8 cm., the distance in each case is somewhat less, and the transition occurred at 2.9 metres.

It is relatively easy to explain a dichromatism which affects a limited portion of the retina such as the fovea centralis. One can suppose, as Mr Willmer has done, that an essential sensory structure such as that responsible for the blue sensation is absent from this region. It is much more difficult to explain a dichromatism which appears sometimes and not at others throughout a large area of the retina, and seems to vary according to the size and distance of the test object.

An attractive hypothesis would be when objects produce on the retina images smaller than a certain size, the blue receptors which are stimulated become so few in number that their impressions fail to get through to consciousness. I find, however, that this supposition is contrary to the observed facts. If the process taking place was one of blue blindness, then one would expect white objects to appear yellow, since this is the combined result of stimulating the remaining red and green receptors. But such is definitely not the case, for we do not find that white becomes yellow, quite the contrary, it is yellow which becomes white.

In support of the contention that the dichromatism is not caused by blue blindness, the following experiment may be quoted. The observer takes up a position in respect of a yellow test object at which it is just beginning to be confused with a white test object of the same shape and size. He now places a deep blue filter in front of his eyes and looks at the brightly lit sky for several minutes. Having reduced the sensitiveness of his blue receptors by this technique, he suddenly removes the filter from his eyes and without delay critically examines the yellow and white test objects. He finds both of them to be a brilliant yellow, in other words, he gets a result which is entirely different from that produced by a reduction of the size of the test object. Whereas inhibiting more or less completely the blue receptors causes white to become yellow, the dichromatism produced as a result of reducing the size of the test object causes yellow to appear white.

When test objects having colours other than yellow are investigated, it will be found that the following changes occur: red and orange remain unchanged, yellow, yellow-green and green have blue added to them, blue-green remains unchanged, blue, violet, mauve and crimson have blue subtracted from them.

It seems that the addition of blue to some colours and its subtraction from others points to the existence of quite a complicated mechanism which sharply differentiates the colours. This mechanism may depend on the brightness of the colours, since yellow, yellow-green and green are relatively bright colours, whereas blue, violet, mauve and crimson are relatively

dark ones. The fact that blue is added to some colours and subtracted from others accounts, I think, for the fact that white remains unaltered.

Further experiments are in progress in order to determine more exactly the nature of the colour change, and the means by which it is brought about.

I should like to thank J E T, J L de S, G N J and E C T for the trouble they have taken in acting as observers for me

Nutritive Value of Coconut

IN NATURE of September 30, 1944, p 437 occurs the statement "and from these accounts it appears that babies fed entirely on coco-nut prepared in various ways until they are more than eighteen months old may be as healthy as those that are breast-fed"

The kernel of the coconut contains 35-45 per cent of oil, about 15 per cent of carbohydrates and a little less than 5 per cent of proteins of low biological value for infants. The kernel is very indigestible for adults and more so for infants when taken in large amounts, because of the great quantity of fibrous matter it contains.

The commonest preparation in the diets of those who consume much of this nut is 'coconut milk'. This is prepared by kneading grated coconut into two or three lots of water and mixing them together; the emulsion thus formed has much the appearance of cow's milk.

The analysis of coconut milk shows that the greater part of the oil has gone into emulsion with some of the protein and carbohydrates, and the residue of the grated nut contains all the cellulose and other indigestible matter of the kernel. It must be in this form, perhaps after mild fermentation, that coconut is given to infants. Supposing an ounce of grated coconut is used to prepare two ounces of milk, then the milk will contain less than 0.5 gm. of protein, about 5 gm. of fat and 1.5 gm. of carbohydrates per oz; there will be about as much sodium chloride and about half as much calcium as in human milk. Coconut is notoriously deficient in vitamins, and the milk contains a little thiamine, probably enough to deal with the metabolites from the small amount of carbohydrates in the milk, but there are only traces of carotene and ascorbic acid.

Undoubtedly biological adaptations have taken place, whereby some races are able to digest and find ample sustenance in foodstuffs which would not bring health and longevity to peoples of some other races. Probably coconut milk can supplement human milk to a small extent. It is, however, difficult to believe that the infants of any race can be weaned and thrive for a year or more on an oily diet deficient in proteins and calcium and containing only traces of vitamin A (carotene) and ascorbic acid.

Statements concerning native diets in many parts of the world are often at variance with our newer knowledge of nutrition, very little knowledge exists

of the dietary habits of the races of the world. There is an urgent need for dietary surveys to be carried out by scientific workers well acquainted with the difficulties of the subject. Such surveys will be of the greatest importance to supplement and perhaps modify some of the present views on human nutrition founded to a great extent on animal experiments. But all such surveys must be accompanied by surveys of the growth and state of nutrition of all classes among each people.

LUCIUS NICHOLLS.

THE term 'coconut milk' is usually applied to the fluid contained in the centre of the nut. It seems to have a very low nutritional value, containing only about 0.4 per cent of protein, 5 per cent of carbohydrate and a negligible vitamin and calcium content. Its calorific value is only about 20 per 100 gm.

The flesh of the fresh coconut, on the other hand, contains, according to the figures I have by me, a little more than 4 per cent of protein, which is certainly of poor biological value, about 39 per cent of fat and rather less than 9 per cent of carbohydrate, giving the relatively high calorie value of 400 per 100 gm. The calcium and iron contents are low. The only vitamin analyses I have for the flesh of the fresh fruit show a very small vitamin B₁ content of 0.03 mgm per 100 gm and about 2 mgm of ascorbic acid per 100 gm. Vitamin A, either preformed or as carotene, is almost certainly absent.

Broadly speaking, therefore, the criticisms contained in Dr Nicholls' letter can be sustained.

J C DRUMMOND

Linoleic Acid, α -Tocopherol and Other Fat-Soluble Substances as Nutritional Factors for Insects

It is now well established that, for growth, insects require a sterol in the diet. We have now established the need for other fat-soluble factors in experiments on the nutrition of a number of insects. Thus the caterpillars of *Ephestia kuehniella* grow very badly on an artificial diet consisting of casein, glucose, yeast, cholesterol, salt mixture and water. A few reach the pupal stage after a long time, but moths invariably fail to emerge. With *Ephestia elutella*, growth is relatively better on such a diet, but again, the moth fails to emerge. This deficiency is entirely overcome by adding wheat germ oil in quantities of approximately $\frac{1}{2}$ -1 per cent of the diet.

We have saponified wheat germ oil and tested the two resulting fractions (saponifiable and unsaponifiable) separately and combined. With both these fractions growth is as good, or almost as good, as with wheat germ oil. With the saponifiable fraction alone, *Ephestia kuehniella* still grows rather slowly, but those which reach the pupal stage ultimately emerge as normal moths. With *E. elutella* growth is almost as good as with wheat germ oil, and emergence is normal. In the presence of the unsaponifiable fraction alone both species grow very badly, and the few moths formed never emerge. Thus it appears that *Ephestia kuehniella* requires two factors contained in wheat germ oil, one saponifiable and the other unsaponifiable, while *E. elutella* probably requires only the saponifiable factor.

Further tests have made it beyond doubt that the saponifiable factor is linoleic acid. With linoleic acid and the unsaponifiable fraction, the moths of *E.*

clutella and *kuehniella* always emerge. If linoleic acid is added to the diets in insufficient quantities moths emerge, but are incompletely developed and the wings are partly or entirely lacking in scales. By adding graded doses of linoleic acid to the diet, all transitional stages between failure to emerge and normal moths can be produced, namely, deformed moths with naked wings, normal moths with naked wings or with wings more or less patchy. The same result has been obtained with graded doses of wheat germ oil. Imperfect moths are also formed when the diet contains oils poor in linoleic acid, such as coconut oil, allenblackia oil or lard.

The unsaponifiable factor in wheat germ oil which is required by *E. kuehniella* is almost certainly vitamin E. A diet which contains the saponifiable fraction of wheat germ oil or linoleic acid is greatly improved by the addition of pure α -tocopherol, in some cases even more than by the addition of the unsaponifiable fraction. There are, however, indications that the favourable effect of vitamin E is not specific. Lard, which is considered to be lacking in vitamin E, certainly contains something as efficient as the unsaponifiable fraction of wheat germ oil, if not more so. Finally, we have succeeded in demonstrating that ethyl- or propyl-gallates have an effect the same as, or similar to, vitamin E. This would suggest that the effect of the unsaponifiable factor is not a specific one, but that of an antioxidant which stabilizes linoleic acid.

There are, however, indications that linoleic acid plus a suitable antioxidant are not the only factors of importance concerned in this reaction. If it were merely a matter of having sufficient linoleic acid in the diet and having it efficiently stabilized, one would expect that growth-rate and degree of scaliness of the wings would go together, so that the growth-rate would always be high where the moths are normal, and always low where the wings are scaleless or patchy. This, in fact, is not the case. With the saponifiable fraction alone, growth of *E. kuehniella* is slow, but the moths are perfect, while with lard, growth is fast but the wings are imperfect. This suggests that a third factor must be involved in the reaction.

The consequences of a lack of linoleic acid, namely, failure to emerge, or emergence of moths with the scales missing to a greater or lesser extent, are different expressions of the same condition. The moth inside the pupal skin seems to develop normally until emergence, with the scales formed on the wings. When the moth emerges, the missing scales are always found on the inside of the cast exuvia. In the extreme case, the scales seem to stick firmly to the pupal case not only in the region of the wings but also elsewhere, notably the abdomen, so that emergence is impossible. This shows that a failure of the scales of the moth to separate from the pupal skin is the cause of the abnormal condition, this may be due to failure to excrete sufficient moulting fluid. It is interesting to note that the condition of incomplete wings which arises from a lack of linoleic acid is similar in appearance, if not perhaps identical, to a genetical aberration in *Ephestia kuehniella* described by Kuhn and Henke¹ under the term "Glasflügeligkeit". This perhaps suggests that the physiological action of this particular gene is concerned with the linoleic acid metabolism.

We have so far not succeeded in demonstrating the need for linoleic acid, vitamin E or other fat-soluble factors which are contained in wheat germ

oil in insects other than those belonging to the genus *Ephestia* (*E. cautella* as well as *kuehniella* and *clutella*). The very closely related species *Plodia interpunctella* certainly does not require linoleic acid, and probably none of the other factors. Other insects which we have tested, including about ten species of beetles and moths, do not seem to be in need of any fat-soluble factors in addition to sterols, and this agrees well with recent work on the dietetics of insects which has been conducted in other laboratories.

Acaricidal Property of a New Insecticide, Hexachlorobenzene

FOLLOWING closely on the several recent demonstrations of the considerable insecticidal potency of 'DDT' (dichloro-diphenyl-trichlorethane) it is surprising to find another substance which, on preliminary trial, promises to be at least as good, and in some ways even better than, 'DDT'. Through the courtesy of Imperial Chemical Industries, Ltd., I have recently had the opportunity of carrying out a few trials with a substance temporarily designated '666' which has been recognized for some little time by I.C.I. research workers as possessing unusually active insecticidal properties. This substance, which may now openly be referred to as hexachlorobenzene, has the general formula $C_6H_4Cl_2$, and is a very remarkable compound in that the extraordinary insecticidal properties are held solely by the γ isomer. It is understood, however, that a general statement is shortly to be made by those who have been engaged in the development of this substance as an insecticide, when details on that interesting point will be published.

A few tests recently carried out at this Laboratory on the action of hexachlorobenzene on guinea pig lice showed it to be at least as effective as DDT. It was also found to be exceedingly toxic to the freshwater crustaceans, *Cyclops*, *Daphnia* and particularly to *Diaptomus*; but in whatever other direction this new substance may excel, its action on parasitic acari promises to be one of the most potent, as was indicated by comparative trials carried out on rats severely affected by notoedric mange. In these trials a comparison was drawn between the efficacy of 1 per cent solutions in liquid paraffin, or olive oil, of hexachlorobenzene, benzyl benzoate, tetraethylthiuram-monosulphide ('Tetmosol') and 'DDT'. Of these four substances hexachlorobenzene was found to be much the most active, and, apparently, without any danger to the treated animals. 'DDT', on the other hand, showed very little effect, and in a second series of trials, when used in 2 per cent strength, led to the death of some of the experimental rats after the development of marked hyperaesthesia and frequent clonic muscular spasms.

A preliminary cleansing of the affected parts of the rats with soap and water was not carried out in these tests, nor was the whole surface of the body treated with the dressings, which were applied only to the affected (hairless) parts. As complete cure

was brought about under these relatively difficult conditions, and living mites were not found in the old lesions, it is thought that in all probability hexachlorobenzene will ultimately prove to be of great value in the treatment of psoroptic scabies (including 'sheep scab') in animals, and of sarcoptic scabies in animals, and also in man

'D.D.T.' as a Sheep Blowfly Dip

THE powerful toxic action of 'D.D.T.' on many species of flies has made possible a new method of attack against the sheep blowfly *Lucilia sericata* (Mg) and related species. As the following experiments indicate, control may be achieved by the direct action of a 'D.D.T.' dip on the blowfly while the insect is searching the fleece for a site suitable for egg-laying.

The preliminary laboratory experiments were made by Dr E T Burt of the Unit of Insect Physiology (Agricultural Research Council), who showed that sheep wool dipped in an emulsion containing 0.5 per cent 'D.D.T.' was toxic to laboratory-bred specimens of *L. sericata*. The following field tests gave results in keeping with this observation and demonstrated that the toxic effect could take place rapidly enough to prevent gravid females of *L. sericata* from ovipositing on sheep.

Two dipping trials were made on farm flocks consisting mainly of Welsh mountain sheep. In both cases the same dipping procedure was adopted and the same 'D.D.T.' emulsion (M 21) used.

In the first trial eighty-one sheep were dipped, the concentration of the bath falling from 0.3786 to 0.3264 per cent 'D.D.T.' in the course of the dipping. The sheep remained free from strike throughout the period of the experiment, August 8–September 18, a total of forty-two days. It was not possible to have a control group grazing with the experimental flock, but chemotropic experiments made on this particular farm indicated that conditions for strike were better in August and September than in the four weeks prior to dipping, when ten strikes were recorded in the flock. Further, bad cases of maggoting were reported on neighbouring flocks.

The second trial comprised a total of 430 sheep grazing on five different regions of one farm. Each grazing unit was divided into two equal groups as regards breed, age and sex. One group was dipped with the 'D.D.T.' emulsion and the other with a commercial arsenical dip. The 'D.D.T.' concentration fell from 0.4540 per cent to 0.2388 per cent in the course of the dipping.

The experiment lasted from August 29 to October 13, a period of forty-four days. Three strikes occurred on 'D.D.T.'-dipped sheep, one of these was a re-strike. Twenty-one strikes occurred in the control group which had been dipped with the commercial preparation, no re-strikes were recorded in this group. In the control group the first strike occurred six days after dipping and in the 'D.D.T.' group twenty-four days after dipping, by which time thirteen strikes had been recorded on the controls.

The following experiments clearly show that the effectiveness of the dip lay in its direct action on the blowfly.

Three weeks after dipping, specimens of *L. sericata* were captured from undipped and 'D.D.T.'-dipped sheep. Of twenty-five flies caught on the undipped sheep, two died in twenty-four hours. Of thirteen caught on the 'D.D.T.' group, nine died in twenty-four hours. All the flies which died, including those caught on the control group, showed symptoms of 'D.D.T.' poisoning within 15–30 minutes of capture. A similar test five weeks after dipping showed one death out of sixteen flies captured on the controls and five out of sixteen captured on the 'D.D.T.' group.

Tests in which gravid females of *L. sericata* were kept in contact with the fleece of a 'D.D.T.'-dipped sheep showed that even five weeks after dipping, 30–60 seconds contact was sufficient to have a toxic effect on the flies.

The action of the dip in preventing oviposition was clearly demonstrated by tests with artificial attractants. The Hobson¹ technique was employed, and five 'D.D.T.'-dipped with five undipped sheep were used in each experiment.

NUMBER OF EGG BATCHES LAID IN REGION OF ATTRACTANT

Date 1944	No of days after dipping	Sheep dipped with 'D.D.T.'	Control group undipped

" 21	43	0 0 0 0 0	3† 2† 0† 0† 0†

* From 3–6 scattered eggs laid, except in the case on September 19, when 15 eggs were found.

† The sheep used as controls on September 21 had been dipped with a proprietary arsenic dip on September 19.

The accompanying table summarizes the results obtained. On no occasion was a complete and compact batch of eggs laid on the 'D.D.T.'-dipped sheep, whereas oviposition was invariably induced on the control group. The results obtained on September 21 are of particular interest because the control group had been dipped with a proprietary arsenic dip only two days previously and their fleeces were sticky and had a strong odour, yet oviposition occurred on them but not on the sheep which had been dipped with 'D.D.T.' some six weeks previously.

In the course of the 1945 blowfly season, the dip is to be given extensive field trials and attempts are to be made to increase its effectiveness by combining an attractant with it, thus making the dipped sheep act as blowfly traps.

I wish to thank Mr L Davies for assistance with the field experiments and Dr J G Mitchell of the DSIR Chemical Laboratory for the preparation of the 'D.D.T.' emulsion and for determining the 'D.D.T.' concentrations mentioned above.

Hydrogen Sulphide Gas as a Preventive of Putrefaction

IN a collection of old microscope slides recently re-examined, a series came to light illustrative of observations made by me some twelve years ago and not hitherto published. They are perhaps of sufficient interest to be put on record now.

During the course of work on the sterilization of dried hides from anthrax¹, the lines of which were suggested by observations by Andriewski², on the toxicity of hydrogen sulphide for anthrax spores, it was found that anthrax spores could be killed by exposure in anaerobic jars to an atmosphere of this gas.

To find out whether hydrogen sulphide was toxic in the same conditions to other micro-organisms and might therefore delay or prevent putrefactive changes, the following experiment was done. Pieces of raw hide newly removed from the animal were put in anaerobic jars—either suspended or laid in petri dishes. The air in the jars was then exhausted by means of a vacuum pump and hydrogen sulphide run in from a kip—being passed first over 1 per cent caustic soda to remove any trace of hydrochloric acid that might be present. The jars were allowed to stand at room temperature or at 37° C. Cuttings from the samples under treatment were taken at intervals, sectioned, stained and compared with cuttings from the same hide kept in air in similar jars at the same temperatures. The hydrogen sulphide jars were refilled at once with the gas after each time of opening.

It was found that in the pieces kept in an atmosphere of hydrogen sulphide, putrefaction was almost entirely checked for a period of at least a week at 37° C. and a month at (approximately) 20° C. One hydrogen sulphide jar was kept sealed (and forgotten) for eight years. At the end of that time the sample of hide was still moist and sufficiently intact to be sectioned, and though the epidermis and cellular structures in general had disappeared and there was considerable breakdown of the fibre bundles, the main outlines of the hide structure were still traceable.

Fig. 1.

Fig. 2.

Fig. 1. OX HIDE KEPT FOR THREE DAYS IN AIR AT 37° C. IN A SEALED JAR.

The epidermis and all the other cellular structures (sebaceous and sweat glands, linings of hair follicles and interstitial cells) have disappeared. The fibre bundles are loosely woven and are showing signs of breakdown.

Fig. 2. OX HIDE KEPT FOR SEVEN DAYS AT 37° C. IN HYDROGEN SULPHIDE IN A SEALED JAR.

The epidermis and other cellular structures are intact or practically so. The fibre bundles are compactly woven and show little or no sign of degeneration.

The accompanying photomicrographs illustrate the condition of the air-treated sample after three days at 37° C. and of that treated with hydrogen sulphide after seven days at the same temperature.

Unfortunately the section shown in Fig. 1 was cut in the direction of the hair follicles and that shown in Fig. 2 across their main direction. In spite of this, however, the much better state of preservation of the sample shown in Fig. 2 is obvious.

Vernalization of Rice by Short Days

IN a previous communication¹, the effectiveness of the method of vernalization of rice by short days has been reported. The method has been tried further with several varieties of rice grown in Bengal, and interesting results of agricultural importance in one winter variety, 'Rupsail', have been noted.

Flowering duration of this variety has been reduced from 133 to 47 days by this method. So far as we are aware, flowering of winter varieties of rice within such a short period has not been reported previously. By applying short days to several varieties of rice, Alam² came to the conclusion that all varieties require a minimum period of 30 days for vegetative growth and a succeeding period of about 30 days of short-day treatment for coming into flower.

This acceleration of flowering has great possibilities for the cultivation of rice in Bengal. First, a variety of fine rice could be grown in a much shorter time; secondly, by inducing early maturity, it could escape flood; and thirdly, early harvesting would leave sufficient time for the preparation of fields for the crops following in rotation.

A full report of this work will be published elsewhere. We wish to express our thanks to Prof. S. P. Agharkar for encouragement and facilities to carry out this investigation.

Two New Records of *Sphacelia* from Mysore

IN the course of his studies on the sugary disease of *Sorghum vulgare* caused by *Sphacelia Sorghi* McRae, Ajrekar¹ recorded three other wild grasses, namely, *Andropogon caricosus* var. *mollicomous*, *Ischaemum pilosum* and *Pennisetum alepecurus* as having the *Sphacelial* stages of an ergot. Sclerotial stages were observed by him only on the last-named host, and he pointed out that heavy infestation by a species of *Cerebella* competed with the formation of sclerotial stages in other cases.

Collections of ergot on wild grasses in Mysore I have made included *Sphacelial* and sclerotial stages

1. SPORES OF *Sphacelia* on *Brachiaria distachya*. 2. SPORES OF *Sphacelia* ON *Amphilophis pertusa*. $\times 1800$.

tion, which at first is translucent, later on hardening into a whitish crust associated with saprophytic yeast cells. Numerous oblong-ovate spores (which are slightly arcuate and slightly pointed at the tips) of the *Sphacelia* become embedded in the nectar. The spores measure $12.6-19 \times 3.8-6.3 \mu$. Subglobose to spherical sclerotia are formed only in a few cases unaffected by *Cerebella*. In the absence of germination stages of the sclerotia, the identity of the *Claviceps* species remains obscure.

The *Sphacelial* stages on *Amphilophis pertusa* are also restricted to individual florets. Partial development of sclerotia due to infestation of *Cerebella* have been observed in some cases. The conidiospores are numerous, hyaline, borne on conidiophores developed as a felt on the surface of the ovary. The spores are distinctly triangular, somewhat rounded at the ends, measuring $8.8-11.4 \times 6.3-7.7 \mu$. Such a type of triangular spores is at variance with the *Sphacelia* of *Claviceps* species recorded both on members of Gramineae and Cyperaceae. On account of the differences in size and shape of the spores, the name *Sphacelia Amphilophidis* is tentatively proposed for the accommodation of the fungus. Detailed description and diagnosis of the species are being published separately.

Grateful thanks are due to Dr. L. N. Rao, professor of botany, University of Mysore, for kind encouragement.

Scattering of Light in Crystals

SINCE its discovery¹, early in 1928, the scattering of light with altered frequency has been investigated in many crystals, and much valuable information has been accumulated. The significance of the results and their relation to theories of the solid state are clearly matters of great interest.

The outstanding result of the experimental studies is that the atomic vibration spectrum of crystals in the infra-red region reveals itself in light-scattering as a set of discrete frequencies, the approach to monochromatism being the more complete the more perfect the crystal, and the lower the temperature at which it is studied. It is particularly significant

that this feature obtains not only in respect of the so-called internal vibrations of the ions or molecules comprised in the crystal, but also in respect of their translatory and rotatory oscillations which are characteristic of the crystalline state. As a typical case, calcite may be mentioned. Dr. R. S. Krishnan has recorded extremely intense spectra with this crystal employing the 2537 Å. radiations of a water-cooled, magnet-controlled quartz mercury arc as the exciter and giving prolonged exposures. Besides the internal vibrations of the CO_3^{2-} ions and their translational and rotational oscillations, octaves and combinations of these frequencies are also found recorded in the spectrum. All of them appear as sharp lines, but not a trace of continuous spectrum is noticeable on the plates.

Comparative studies with various substances in the molten and solid states make it clear that every mode of infra-red vibration which gives rise to appreciable variations of optical polarizability in the volume elements of a crystal also manifests itself as a frequency-shift. Hence, as in the cases of gases and liquids, we are entitled to infer that the spectrum of light-scattering in a crystal is a faithful map of the fundamental infra-red vibration spectrum, excepting only the modes for which the symmetry excludes any variation of optical polarizability.

Recently, by a straightforward dynamical investigation², I have shown that the fundamental vibration spectrum of a crystal containing p sets of non-equivalent atoms consists of the $(3p-3)$ modes which repeat themselves in adjacent cells of the Bravais lattice, and in addition $21p$ other modes in which the phase alternates in successive cells. The prediction confidently made that these $21p$ modes should also manifest themselves in light-scattering has been strikingly confirmed by Dr. R. S. Krishnan³ in the case of diamond.

It is clearly impossible to reconcile the facts stated above with the theories of the solid state which assume, or claim to show, that the atomic vibration spectrum of a crystal in the infra-red region is a continuous one. To effect any such reconciliation, it would be necessary to invent a mechanism which could transform the assumed continuous spectrum of frequencies into a discrete line spectrum by a process of exclusion. One such mechanism which has often been suggested is that the phases of the infra-red vibration are perfectly coherent over the whole volume of the crystal, in consequence of which all the scattered radiations disappear by optical interference except those arising from the so-called limiting modes of vibration, $(3p-3)$ in number, the phase wave-lengths of which are comparable with the length of the light waves and satisfy the Bragg condition for reflexion. To this suggestion, however, there is a fatal objection, namely, that $21p$ other modes which have much smaller phase wave-lengths not satisfying this condition are also observed in light-scattering, while the infinitely numerous others which are also assumed to exist in the aforesaid theories fail to manifest themselves. A further objection is that, in actual crystals, the assumed coherence of phase can scarcely be expected to extend over sufficiently great volumes for optical interference to be effective. For the latter reason, the continuous spectrum assumed to exist in such theories should manifest itself fully in light-scattering or at least give an observable indication of its existence. Since this is not the case, we can only infer that the postulated continuum does

not exist in the infra-red region of frequency. We are, of course, here not discussing the low-frequency or elastic solid vibrations in which the discrete atomic structure is not explicitly involved

X-Ray Crystallography of Kojic Acid

AT a time when its identity was uncertain, specimens of the compound isolated by M. A. Jennings and T. I. Williams¹ from *Aspergillus effusus* were examined in order to determine its molecular weight. The compound was later shown to be kojic acid. It forms monoclinic needles elongated along [100] and showing the forms {100}, {010} and {021}. The following data for the unit cell were obtained from X-ray oscillation photographs: $a = 3.85$, $b = 18.4$, $c = 8.84$ Å, $\beta = 74^\circ$, correct to about ± 1 per cent.

Absent spectra indicate that the space group is $P 2_1/c$ and the density determined by flotation in an ethylene dibromide-bromobenzene mixture is 1.559 ± 0.006 . The space group allows any even number of molecules in the cell, and if four molecules are assumed the molecular weight is 142 ± 3 . This value is in good agreement with the formula $C_6H_6O_4$ (mol wt 142) and with the quantitative analysis and cryoscopic determination of F. Traetta-Mosca².

Long Duration of the Balmer Spectrum in Excited Hydrogen

LORD RAYLEIGH has reported recently¹ the results of a new experimental determination of the duration of the emission of hydrogen Balmer lines, H_α , H_β and H_γ . Hydrogen (pressure 0.2 mm mercury) was excited by an electrodeless discharge in a tube having the form of a square ring connected with a side tube, through which it was exhausted. Each discharge (of very short duration) produced a luminous jet squirting out of the discharge space, along the tube. The light emitted by the jet contained the Balmer lines in question. From the measurements of the speed of the jet (by means of a revolving mirror) and of the decay of luminosity at various distances along the tube, the durations of these lines were determined. In some conditions they appeared to be roughly one thousand times greater than the values calculated theoretically as well as those given by previous experiments. As Lord Rayleigh states, the difference of behaviour of the lines is not very marked, and not always noticeable.

Since, presumably, one of the purposes of Lord Rayleigh's paper was to rouse discussion, I should like to put forward a possible explanation of his unexpected

results. The mean duration of lines is not always identical with the mean life in initial states of corresponding transitions. This would be the case only if no transitions from higher levels to the initial level of the line (cascade transitions), no recombination of ions, no transfer of excitation energy from atoms or molecules in metastable states, no 'imprisonment' of radiation, etc., took place. From these possibilities the first two, namely, cascade transitions and recombinations of ions, seem to be not excluded in Lord Rayleigh's experiments. Thus the most probable cause of the prolonged duration of the H_α , H_β and H_γ lines seems to be the recombination of atomic hydrogen ions.

Vibration in Telegraph Wires

Two winters ago while motoring over a route traversed daily for many years, we observed this phenomenon for the first time. Hence the conditions, giving rise to it must be rather exceptional. The vibration was so striking and unusual that we stopped the car to exclude the possibility of adventitious optical effects from that source. The time was about 9.15 a.m., the air clear and 'frosty', the sun brilliant, and the wires heavily loaded with ice. There was a barely perceptible breeze blowing across the road.

On the left side of the road were the usual telegraph wires, and on the right a group of four thicker insulated wires carrying lighting current. Both sets, although obviously under very different degrees of tension, were vibrating with considerable amplitude. The effect was general over several miles of road. Ultimately the right-hand wires changed direction and ran off sharply at right-angles to the road (that is, parallel to the wind stream). No vibration could be observed in this stretch. Later we ourselves turned right (that is, down wind) and here the standard telegraph wires also ceased to show any vibration.

In attempting an explanation several factors were reviewed. (1) The physical effect of temperature on the vibrating system, as defined by the 'sonometer' formula, can be ignored, as a drop of 40°C only affects the rate by about 0.1 per cent. (2) From the dissimilar behaviour of the wires orientated across and parallel with the wind stream, we may safely presume that this cross flow is an essential factor. (3) Genesis from some random specific 'air velocity vibration resonance' correlation may be excluded, as two entirely dissimilar sets of wires were simultaneously in vibration.

In view of the above, we reached the conclusion of Gilbert *et al*¹ that the vibration is initiated and maintained by the differential pressure effects resulting from an air flow across a wire of non-circular section, that this abnormal source of energy explains the abnormally high amplitude, that the visual effect is aided and intensified by the greatly increased thickness of the wires, and by the loading of the wires reducing the vibration rate below the threshold at which the persistence of vision obscures observation².

What surprised us at the time was that, despite the obvious relationship to a cross wind, the prevailing breeze was almost imperceptible

Effect of Substituents on the Oxidation Potential of Ferrous *ortho*-Phenanthroline Complexes

IN a recent communication¹, Smith and Richter have measured the oxidation-reduction potentials of a series of substituted *ortho*-phenanthroline iron complexes

The values obtained show a marked trend with the dipole moments of the corresponding substituted benzenes. More striking, however, is the fact that a linear graph is obtained when these formal oxidation-reduction potentials are plotted against the (negative) logarithms of the dissociation constants² of the corresponding *para*-substituted benzoic acids

E_0 and $\log K_a$ are, of course, proportional to the free energy changes of the corresponding reactions. Clearly, an electron shift, for example one towards the substituent group, which in the acid series raises

X	E_0 (volts)	pK_a
NO_2	1.25	3.42 ₅
Br	1.12	3.97 ₁
Cl	1.12	3.97 ₇
H	1.06	4.20 ₃
CH_3	1.02	4.37 ₃

The equation to the line is $E_0 = 2.082 - 0.243(pK_a)$

the acid strength by increasing the repulsion on the proton, is similarly transmitted in the complex ion. The withdrawal of electrons is communicated through the co-ordinated nitrogen atoms to the central iron atom, to produce an increased binding of its electrons and a proportionate rise in the oxidation potential

Causality or Indeterminism?

I HOPE it will not cause *Nature* to lose caste for a very ordinary man to join in the discussion on causality v indeterminism so ably dealt with by Prof H. T. H. Piaggio, and to express thoughts that will at least be understood by all who try to read the exceedingly specialized correspondence columns

I follow the line of argument that coin tossing is not really haphazard but governed by strict laws of causality, although the variation in launching and wind may be impossible scientifically to calculate. Incidentally, the alternative of red and black on a roulette board is the incalculable ideal, in that the ball launched round the board in the opposite direction to the spinning centre has to strike odd-shaped obstacles before rolling into the middle. Results have, I understand, for some obscure reason been chronicled for years.

When we come to atomic physics we get into heavy weather and we are not really helped by von Neumann's six laws, especially the one referring to the 'squared operator' which may convey that there is something wrong with the 'tote', but is otherwise entirely incomprehensible to the layman. Anyhow, at present the pundits plump for indeterminism.

How can this refreshing individuality in atomic physics, so stimulating in our dragooned world, react on 'homo sapiens' (sic)?

In Schrodinger's attractive book "What is Life?" with Darlington prompting him 'off', as they say on the stage, he tells us that we mortals are made a certain size in order that statistical results should obtain. A serious corollary, however, emerges in that genes are so small as to be subject to random changes as, for example, in the energy-level of their few constituent atoms. These changes are enough to account for mutants. Through no fault of our own, therefore, we may become the parents of monsters. May we now go further and be told by those who analyse the micromechanism that animates the brain whether there are there, constituent parts of such small size as also to be influenced by random atomic changes. If such be so, then the truly awful thought faces us, that all our wise decisions, all our noble or possibly questionable actions in life, are determined, not by our own high-charactered and noble 'ego', but by a microscopic atomic material part of our brain, over which we have no control, being bumped around on the quantum level.

These are grave thoughts, but if the latter hypothesis be true, although not exactly comforting, it would at least explain and indeed excuse many mistakes made in life by your obedient servant,

BRABAZON OF TARA

RESEARCH ITEMS

Origin of South American and African Freshwater Fishes

WILLIAM A GOSLINE (*An Acad Brasil. Ciencas*, 16, No 3, 1944) criticizes some of the arguments advanced by biologists who have marshalled geological evidence to agree with their own interpretation of the biological data. While the author does not attempt to offer final conclusions concerning the African and South American freshwater fishes, he summarizes the evidence supplied by the best-known freshwater group, and suggests lines of further investigation. These are included under four heads (1) The compilation of up-to-date revisions of the groups of fish involved, together with the presentation of phylogenies of these groups based on palaeontological, anatomical and physiological data. These would show the relationship of the fishes between areas as compared with those within areas (2) The demonstration from various sources of evidence that certain groups have originated and evolved in fresh water, and that salt water has always formed a complete barrier to their dispersal (3) The determination, so far as is possible, of the geographical distribution—past and present—of these groups, together with their ecological limitations (4) The correlation of all material from the above lines of investigation, special account being taken of the environmental needs affecting fish dispersal, with the derived data for other animal and plant groups and with geological and climatic history

Growth Hormones in Tetraploids

F. G GUSTAFSON (*J Hered*, 35, 269, 1944) has shown that tetraploid marigolds have 58 per cent and 76 per cent as much growth hormone as their related diploid, while the autotetraploid *Lycopersicon pimpinellifolium* has 56.8 per cent of that of the diploid. This reduction in amount of growth hormone may be related to the well-known time differences in growth between diploid and tetraploid plants

Mitosis and Cell Differentiation in the Blood

L F LA COUR (*Proc Roy Soc Edin*, 62, 73, 1944) has used new technical methods to investigate the chromosome behaviour and nuclear cycle in the origin of blood cells in man, mice, rats, cats and dogs. There is a unique difference between the precursors of myelocytes and erythrocytes in respect of the nucleic acid content of the nucleus. The pre-erythrocyte cells stain an intense red by the Pappenheim stain, whereas the pre-myelocytes stain pink. Similarly the chromosomes of the first type show a greater desoxyribose nucleic acid charge. In man with pernicious anaemia, the differences are accentuated. This leads on one hand to over-spiralization and abnormal division in the overcharged erythrocytes, and long thin chromosomes, incompletely spiraled in the myelocytes. As a result of the abnormal divisions with multiple spindles and chromosome bridges, the daughter cells often contain irregular chromosome numbers. Hypoploid cells have been found in the normal field mouse. Nucleoli are present in all precursor cells in the marrow and are later replaced by heterochromatin. Their presence is correlated with cell proliferation. The matured myelocytes in the mouse and the rat are tetraploid as a result of an abortive anaphase of the last division. White tetraploid cells occur in association with a

shortage and red tetraploid cells with an excess of both nucleic acids in pernicious anaemia. Evidence is given which suggests that the enucleate condition of mature erythrocytes is due to the extrusion of nucleic acid and not of the nucleus

Pre-harvest Drop of Apple Fruit

PRE-HARVEST drop of apple fruits which have reached or almost reached picking maturity is a serious problem confronting apple growers in America and, to a lesser extent, in Great Britain. Innumerable trials carried out in recent years have indicated that some control of this trouble may be effected by spraying the trees, shortly before picking maturity is reached, with growth-substance solutions. The standard spray used contains ten parts of growth substance per million of spray, but L Southwick reports (*Proc Amer Soc. Hort Sci*, 42, 199, 1943) that stronger sprays may be more effective and that, while dusts which can be applied more easily are as effective as solutions with some varieties, they are less effective with others. Southwick, like M B Hoffman, A V Doren and L J Edgerton, finds dusts as effective as sprays with McIntosh apples. The addition of spreaders to the sprays is not necessary, but the sprays are ineffective if their application is followed by a spraying with water (or presumably rain) within two hours (E L Overholser, F L Overley and D L Allmendinger, pp 211-219). Sprays given near midday are most effective, and the period of effectiveness may be as much as twenty-eight days, but is less if temperatures are high. The hormone sprays are without any direct effect on the firmness of the fruit or development of decay, breakdown and scald in store (M H Haller, pp 207-210), but by delaying picking they may improve colour and taste and increase the size of the fruit as harvested by permitting the attainment of greater maturity (E P Christopher and S A Pieninzek, *ibid*, 43, 29, 1943)

Mercury for Grain-Pest Control

THE method of grain-pest control as practised by the rayats in certain parts of India involves the use of mercury. It concerns the protection of stored pulses against the bean beetle, and for this purpose a drop of mercury is placed in an excavated soap nut and lodged in the storage container. D W Wright, of the School of Agriculture, Cambridge, has made an attempt to assess the efficacy of mercury for the control of several of the commoner grain pests (*Bull Entom Research*, 35, 143, 1944). Experiments showed that the vapour of mercury was fully effective in preventing reproduction of the grain weevil (*Calandra granaria*), the saw-toothed grain beetle (*Oryzaephilus surinamensis*), the lesser grain borer (*Rhyzopertha dominica*), and the Angoumois grain moth (*Sitotroga cerealella*). Zinc and tin amalgams and calomel were less effective than metallic mercury. The efficacy of a given weight of mercury is increased by subdivision, a process which increases its total surface area. The substances used were found to emit a vapour which contained free mercury. Storage of insects in mercury vapour was found to have no effect on the viability of grain weevils, neither did it influence their subsequent reproductive capacity. The action of the mercury was on the eggs, which failed to hatch. Germination and spectroscopic tests on grain that had been stored for several months with mercury gave no indication

that any contamination had occurred. The grain weevil was able to breed vigorously in grain so treated.

Crocidolite Asbestos in Western Australia

BLUE amphibole (riebeckite) asbestos occurs in seams interbedded with banded ironstones of Nullagine age in the Hamersley Ranges of Western Australia. The petrology of the deposits and the associated rocks has been described by K. R. Miles (Geol. Sur. W. Aust. Bull. 100, 1942), and there is also a report on the economic importance of the occurrences by J. S. Foxall. The banded ironstones include sideritic cherts, magnetite- and hematite-bearing cherts and banded jaspers associated, as usual, with quartzites. The ironstones are interpreted as chemical sediments in which the bulk of the iron was originally precipitated as ferrous carbonate. Under conditions of low-grade metamorphism, riebeckite has developed in these beds as (a) scattered needles, (b) massed aggregates of needles (potential crocidolite), and (c) seams of uniformly parallel cross fibres (crocidolite proper). In their geological setting, structure, composition and optical properties the riebeckite and asbestos occurrences are closely similar to those of the better-known South African deposits. The chief problem in both areas is the source of the soda required for crocidolization. Riebeckite contains six per cent or more, whereas only traces of soda appear to be present in the adjacent formations. The current hypothesis that crocidolite occupies the place of pre-existing soda-rich layers in siliceous ironstones is therefore far from satisfactory. Another possibility is that soda may have been introduced (as in albite-schists) by emanations from plutonic sources, but the absence of igneous rocks and of regional metamorphism would seem to be inconsistent with this alternative. Both in Australia and South Africa the origin of crocidolite remains a geochemical enigma.

Viscosity of Compressed Gases

THE viscosity η of a non-ideal gas was considered in 1922 by Enskog, whose formula was checked for carbon dioxide and (by Michels and Gibson) nitrogen. $\eta = \eta_0 (1 + 0.175b\rho + 0.86b^2\rho^2)$, where η_0 is the ideal gas viscosity, ρ is density, and b is van der Waals' constant. O. Leipunsky (*Acta Physicochim. URSS*, 18, 172, 1943) has shown that the formula gives quite satisfactory results for a number of gases, with a tendency at high densities to show rather higher values than the experimental, due to the change of b with pressure. The formula is thus of service in technical calculations where compressed gases are concerned. With a suitable value of b the formula also applies to mixtures, where the mathematical theory is extraordinarily clumsy and incomplete.

Absorption Spectra of Substituted Benzene Sulphonamides

ALTHOUGH several publications have dealt with the ultra-violet absorption spectra of sulphanilamide derivatives, little has been done towards identification and characterization of the individual absorption bands. J. M. Vandenberg and L. Doub (*J. Amer. Chem. Soc.*, 66, 1633, 1944) have made a study of simple sulphanilamide derivatives and find that they have one single band of strong absorption (ϵ , about 17×10^3) in the accessible ultra-violet region, about 260 m μ in neutral solution, which shifts to shorter

wave-length when the solution is made alkaline, and decreases in intensity with acidity. Simple substitution which does not change the basic ionization properties of the molecule has little effect on the wave-length of the band. With more complicated substitution, other bands appear. Sulphathiazole has a band at 257–259 m μ with the properties of the sulphanilamide band, and a band at 280–283 m μ which shifts to shorter wave-length in alkali and is not destroyed in 2N hydrochloric acid, and is probably due to the thiazole portion of the molecule. With sulphapyridine three bands are found, at 242, 261 and 311 m μ , the third being due to the pyridine portion. In alkaline solution the maximum at 311 m μ shifts to shorter wave-length and the peaks at 242 and 261 m μ apparently fuse to a single broad band of increased intensity at 245 m μ . With sulphadiazine a 257 m μ band is due to the *p*-aminobenzene sulphonamide absorption and a 241 m μ band to the pyrimidine ring. Such comparisons with simpler analogous compounds make it possible to associate the bands with absorbing groups in the molecules.

Pulsation Theory of Cepheid Variables

P. L. Bhatnagar and D. S. Kothari, Department of Physics, University of Delhi, in a paper "A Note on the Pulsation Theory of Cepheid Variables" (*Mon. Not. Roy. Astro. Soc.*, 104, 292, 1945), deal with certain points raised in Prof. Svein Rosseland's George Darwin Lecture (see *Nature*, 153, 261; 1943). Rosseland developed his theory of 'anharmonic pulsations' and found that the semi-amplitude of oscillation would have to be a quarter of the star's radius—a value which is four or five times too great for most of the Cepheids. The authors of the present paper point out that this and other results obtained by Rosseland are not inherent in the model, but arise because of an approximation introduced in the investigation. They treat the matter in a simpler way than Rosseland, assuming γ , the ratio of the specific heats, to be 5/3, and avoiding the approximation introduced by Rosseland. The conclusion is that the theory of anharmonic oscillations for the above ratio cannot account for the observed skewness in the velocity-time curve of the Cepheid variables. The observed skewness demands a semi-amplitude almost equal to R , whereas the observed value is about 0.1 R , unless the value of γ is assumed to be much greater than 5/3. A rough calculation shows that if the observed skewness is to arise for a semi-amplitude of 0.1 R , γ is comparable to 10.

Van Biesbroeck's Star

It is announced (*Harv. Obs. Card.* 697) that W. J. Luyten and P. D. Jose have found the colour index of Van Biesbroeck's faint companion to BD +4°4048 to be 1.4 and the photographic magnitude 19.5, giving a photovisual magnitude of 18.1. The colour index was derived from blue and yellow plates taken with the 36-in. reflector of the Stewart Observatory. It is surprisingly low for so faint a star (absolute magnitude 19.3 photovisually) and in addition there are several stars in the vicinity which are as red as, or even redder than, the proper motion star. This suggests the possibility that this star, which has the lowest known luminosity, is a degenerate star and approaches a black dwarf. It is remarked that it might be a star the surface temperature of which corresponds to that of an early *M* dwarf, but the luminosity of which is several thousand times lower.

OXIDATION-REDUCTION ASPECTS OF RESAZURIN

By the late R. S. TWIGG

London School of Hygiene and Tropical Medicine
and

National Institute for Research in Dairying

RESAZURIN was discovered by Weselsky¹, and first used by Pesch and Simmert in 1929² for estimating the bacterial content of milk. It has lately been extensively used in Great Britain as a basis for a number of tests for the hygienic quality of milk^{3,4}. Reduction takes place in two stages

In fresh milk, reduction is chiefly due to cells (mastitis, etc.), and in aged (for example, 24 hours old) milk, to bacteria.

Work has been carried out electrometrically at 30° C in the absence of oxygen, on the two stages of reduction

Only the second stage of the second reduction is reversible at an inert electrode.

Electrometric titration curves of resazurin at pH 6.55 compared with curves of the same amount of resorufin at the same pH show that during the first reduction some of the latter is simultaneously reduced to dihydroresorufin (Fig. 1). This is true, at least, between pH values of 6 and 7.

Fig. 1 A, TITRATION OF 20.00 RESAZURIN
B, " " " " RESORUFIN
All solutions 0.000132 M, pH 6.55.

The courses of the oxidation-reduction curves of the reaction $\text{resorufin} \rightleftharpoons \text{dihydroresorufin}$ resemble those of nearly all other reversible dyestuffs in that two electrons per molecule are transferred in the reaction, at any rate at pH values greater than 3.0.

The E'_0 -pH curve, constructed from the table on p. 402, is shown in Fig. 2. All points were taken from measurements made by the 'method of mixtures', but some, including those at pH 6.583, 6.867 and 7.431, have been confirmed by titration.

The curve shows four sections having $-dE_h/dpH$ values of 0.03, 0.06, 0.09 and 0.06 successively from high to low values of pH. This, together with the other chemical aspects, shows that the system conforms to W. M. Clark's formulation $\text{Ox} + 2e = \text{Red}$.

The electrode equation which describes the above findings and agrees with the observed values in the table is

$$E_h = E_0 - 0.03006 \log \frac{[SR]}{[SO]} + 0.03006 \log \left[\frac{K_1 K_2 (H^+) + K_1 (H^+)^2 + (H^+)}{K_0 + (H^+)} \right]$$

The calculated value of pK_0 is 6.93, and of E_0 is +0.380 v. By adopting for pK_1 and pK_2 the values

9.26 and 10.02 respectively, the calculated values are given in the table.

The calculated and observed values agree fairly well, except at pH values of 6.583, 6.867 and 7.431 (of which the first two fall within the normal range of the pH of milk). These three large deviations may be due to low solubility characteristics, but it was deemed unwise to decrease further the concentration of the dye (which is 0.000015 M in the experiments), owing to the ease of re-oxidation of dihydroresorufin by traces of oxygen.

From pH 3 up to the high acidities of hydrochloric

Fig. 2 RELATION OF E'_0 TO pH

acid or sulphuric acid, a blue-green compound, presumably a merquinone, is formed by the reduction of resorufin with titanous salts, or by oxidation of dihydroresorufin with quinone or potassium dichromate. While the reduction method shows that a merquinone having an oxidant:reductant ratio of 1:1 occurs, the oxidation method, curiously, shows a 3:2 ratio.

If a solution of resazurin be acidified to 4.76 *N* with hydrochloric acid, and potassium iodide be added to a final concentration of 0.06 *N*, a spontaneous reduction of the resazurin proceeds not only to resorufin, but also to a further half reduction of the resorufin so formed to the merquinone stage, with the release of the equivalent amount of iodine, which may be extracted with carbon tetrachloride and determined by an iodate titration. On the other hand, if the resazurin be acidified to 3 *N* with sulphuric acid or about 1.2 *N* with hydrochloric acid, and potassium iodide added to 0.06 *N*, only the complete reduction of resazurin, without further reduction of the resorufin so formed, occurs. This difference depends upon the low solubility of resorufin in the medium, and upon the observation that at these high acidities the potential of an iodine-potassium iodide mixture at a inert electrode decreases with increasing acidity which is contrary to experience with other systems.

Commercial resazurin contains variable amounts of resorufin. These latter findings have led to the development of a method for estimating the amount of resazurin in a sample together with any resorufin present as an 'impurity'.

If *A* is the iodine equivalent of the first procedure, and *B* that of the second, then, if *RZ* = resazurin, *RF* = resorufin

$$A = 2RZ + [RZ \text{ (as 'formed' RF)} + RF \text{ (as 'impurity')}] \\ = 3RZ + RF$$

$$B = 2RZ, \text{ or } RZ = \frac{B}{2}$$

$$A = \frac{3B + 2RF}{2}$$

$$\text{and } RF = \frac{2A - 3B}{2}$$

These equations have been verified by electrometric investigations carried out in conjunction with iodine estimations.

I am indebted to the Agricultural Research Council for a grant in aid of this work.

INDUSTRY AND UNIVERSITY EDUCATION

THE proceedings of the Conference of Industrial Representatives on "Industry and University Education", convened by the Vacation Work Committee of the Imperial College of Science and Technology Union on December 15, have now been published. At the first session, on "Post-war Technical Requirements in Industry", Dr P. Dunsheath, in a paper on "Industry's Requirements in Personality", suggested that university education tends to lay too much emphasis on the working of things and to give insufficient attention to human relationships and the working of the mind. University graduates are of much greater value to industry when, in addition to their equipment of mathematical and scientific data, they possess some knowledge of humanity with its intricate and sometimes contradictory relations. Urging that the universities should concern themselves with developing the characteristics making for leadership, Dr Dunsheath emphasized the importance of a sense of proportion and the ability to get ideas understood by others. He believes that more attention should be given to the classification of students according to their real aptitude for research, for design, for production or for teaching. Good brains are required in design and production as well as in research, and above all in teaching. All administrative posts in scientific industry should be filled, he thinks, by those with scientific and technical knowledge of the industry.

Mr E. R. Davies, director of research, Messrs. Kodak Ltd., pointing out that the problems of the industrial research worker always tend to lead him back to problems in pure or applied science which are not peculiar to his industry but of much wider interest, deprecated further specialization during the undergraduate years. More emphasis should be placed on postgraduate work, but the men required should be scientists first and technologists second. He thinks that technologists in the production and distribution sides would be drawn largely from the technical colleges. Although he would welcome the establishment of a university chair in photography, he would prefer to see postgraduate training continued in pure and applied science as it is at present. Its main aim should be to train a man in research methods, but he would like to see some broadening of the basis of scientific training at the graduate stage. There should be the closest possible contact between the universities and industry.

In the discussion, Lord Eustace Percy suggested that industry should find more men within its own ranks who are worthy of a university education and could profit by it. Dr G. M. Dyson referred to the need for thoroughly re-organizing the technical colleges, adequately endowing and equipping them and providing them with sufficient men to cope with teaching and to prosecute research as well. Dr J. A. C. Williams put in a plea for including the philosophy and psychology of engineering in the university engineering course, and for increased use of the technical colleges for refresher purposes.

The second session of the Conference, which considered "Post-war Requirements in Scientific Education", was opened by Prof. L. Bairstow, who pointed out that scientific education cannot be considered adequately as a separate subject apart from the rest of life, and referred to the economic difficulties

attending any extension of a student's career, especially for the majority whose work is less absorbing than research and where compensations are necessary. Specialization, or differentiation, should not come before the third year, and even then should not involve a student being committed to one field for the rest of his life. He believes that we need more training in administration for a limited number of people, who would in due course take their place with those who have studied life from a different aspect. Then we should retain, and possibly extend, a completely free atmosphere for those students who take naturally to research. We also need a better administrative attitude to research, and also technical high-schools and extended facilities in the ordinary technical schools.

Prof H V A Bruscoe confined himself to the question of producing men destined for teaching positions in pure and applied science and in the industries using applied science. He stressed the importance in recruitment of selection and of widening the field of choice, we must look critically and constructively at this question of extended recruitment and make a scientific career attract more of the really good men who at present go into other fields. Then he stressed the importance of excellence in the teaching staff with reference to imparting selected principles and facts in science so as to inculcate and develop intellectual integrity and to display the cultural aspects of science, as well as to the provision of opportunities for special development. Curricula are overloaded, and we must remember that the task is education, not teaching. Lastly, there is the question of assessment and guidance in the valuation of the graduate, so that he does what is best in his own interest and in the interests of the community. Here full co-operation of the employer is essential. With regard to the desirability of having first-class men for production, he believes that the choice between research and production should be left open and that we should aim at turning out keen, properly equipped scientific workers, whose careers would be determined by their aptitudes and opportunities.

Dr R V Southwell, stressing the importance of a real partnership with industry, suggested that we may find that the best arrangement is not one in which three years at a university are followed by two years in industry, but one in which the last of the five years sees a man returning to his university. A man who enters industry should not have finished with his university, and we might well keep a more open mind on the order in which the years are spent between industry and the university.

Mr J W Sawtell emphasized the importance of good management, he thinks that we should impress on the universities the need for men with a scientific education who can manage and handle other people, and appreciate the importance and dignity of management as a profession. Mr L P Combes pointed out that regard must be had to the question of national service and its incidence on the age of recruitment. Mr D A Bell thinks that one reason why graduates tend to enter industry only in research departments is that management has not been regarded as a worthy or scientific profession. In written subsequent contributions, Mr W S Flight referred to the economic difficulties of a long period of training and a possible solution through the State bursary scheme, and Mr M I Freeman urged that some training in the principles of industrial administration and

organization should be given by the university rather than by industry.

Dr A J F Welch referred to the importance of vacation work and of having on academic staffs those with first-hand acquaintance with industrial conditions, while Dr F M Potter, urging the value of a sound fundamental knowledge and elementary background of several subsidiary sciences, suggested that students would do well to avoid the tendency to live with men in the same year who are studying the same branch of science.

MODE OF ACTION OF PENICILLIN

IN an article on penicillin treatment in *Nature* (677, Nov 25, 1944) reference was made to the work of Lieut-Colonel J W Bigger (*Lancet*, 497, Oct 14, 1944), who concluded that penicillin actually kills *Staphylococcus pyogenes*. He suggested that it kills them at the time of division and has no effect upon individual cocci which are not dividing. These, therefore, persist in broth cultures, which penicillin frequently fails to sterilize, and are the explanation of that failure. Bigger proposed to give penicillin intermittently, in the hope that these 'persisters' would begin dividing in the intervals of the penicillin doses and so would be killed by the next dose. Bigger refers to the work of C D Gardner (*Nature*, 146, 837, 1940), who found that, in weak concentrations of penicillin, cocci swelled to three times their normal size without division, and bacilli showed similar changes.

E W Todd (*Lancet*, 74, Jan 20, 1945) also refers to this and other work in his report on his experiments on the bacteriolytic action of penicillin. Working with *Pneumococcus* Types I, II and III and with *Streptococcus viridans*, hæmolytic streptococci, staphylococci and *Clostridium welchii*, he found that all the strains of these organisms which he used were lysed by penicillin, but that such organisms as *Bact. coli* and *Pseudomonas pyocyanea*, which resist penicillin, were not lysed by it. But penicillin, he concluded, can kill organisms without lysis. When lysis occurs, its rate depends on the actual or potential rate of multiplication of the organisms. Their multiplication, as G L Hobby, K Meyer and E Chaffee (*Proc Soc Expt Biol*, N Y, 50, 281, 1942) also found, is essential for the action of penicillin. "It would appear that bacteriostasis, bactericidal action and bacteriolysis may be different stages of a single process proceeding in that order." The most rapid lysis occurs with organisms at the maximal rate of multiplication. This may be the real reason why penicillin is so effective, that is, because young actively multiplying cultures are more susceptible to bacteriolysis, so that organisms in the phase which enables them most readily to invade the human body are also then most susceptible to lysis.

These conclusions may be compared with those of Prof L P Garrod (*Brit Med J*, 108, Jan 27, 1945), who agrees that penicillin actually kills susceptible bacteria. He quotes the further opinion of L A Rautz and W M M Kirby (*J Immunol*, 48, 335, 1944) that penicillin is actually bactericidal. Garrod gives, however, only qualified support to Bigger's hypothesis that penicillin is bactericidal only to organisms when they are about to divide, which was, he says, also put forward by G L Hobby and M H Dawson (*Proc Soc Expt Biol*, N Y, 56, 178, 1944) and by C P Miller and A Z Foster (*ibid*, 56, 205).

Against this hypothesis, Garrod maintains, are (1) his experiments on the effects of temperature, like other disinfectants, penicillin is more active at higher temperatures, but is even more active at 42° C, when bacterial growth ceases, than at 37° C, incidentally, Garrod finds that its action is impaired by increase of the acidity between pH 7.0 and 5.0, (2) the fact that bacteria from both old and very young cultures are almost uniformly susceptible. Garrod therefore thinks that there is no conclusive evidence in support of Bigger's proposal to give penicillin intermittently, and claims that clinical experience supports his view. Penicillin treatment fails because the organisms are inaccessible inside necrotic areas or in undetected abscesses.

Further important conclusions drawn by Garrod are that nothing is to be gained by using higher concentrations of penicillin (cf Sir A. Fleming, *Lancet*, 621, Nov 11, 1944, see also *Nature*, 155, 341, March 17, 1945), especially in local treatment. The idea that higher doses will be more effective does not apply to penicillin. The reverse is truer. A concentration of 1 unit per c.c. is not only just as effective as one of 1,000 units, but is often more effective. The only good reason for using stronger solutions in local treatment is to ensure that the concentration does not fall below the minimum fully effective level of about 0.1 unit per c.c. Garrod further emphasizes the importance of the purity of the penicillin which is being used experimentally. He found that all commercial penicillins tested were less active in higher than in low concentrations. Presumably impurities were responsible for this, and they cause serious obstacles to the study of the action of penicillin. It will be necessary to find out whether penicillin is a single substance of unvarying composition and uniform action.

Discussing these results in a valuable leading article, the *British Medical Journal* (123, Jan 27, 1945) directs attention to the enormous variation in the susceptibility of various bacteria to penicillin. Some species classed as totally resistant are affected by higher concentrations of penicillin, for example, the typhoid bacillus and the salmonellas. H. F. Helmholz and C. Sung (*Amer. J. Dis. Children*, 68, 236, 1944) have found that some resistant bacteria in the urine are affected by high concentrations, for example, *Proteus* and some strains of *B. coli*. Only *Bact. aerogenes* and *Pseudomonas pyocyanea* remained unaffected. The treatment of some infections of the urinary tract with penicillin might thus be effective. E. W. Todd, G. S. Turner and L. G. W. Drew (*Brit. Med. J.*, 111, Jan 27, 1945) have found that *Staphylococcus* strain Oxford H can be trained by growth in increasing quantities of penicillin to become 3,000 times more resistant to penicillin than it originally was. Similar results were obtained with another strain of *Staphylococcus*. Unlike other organisms which become 'drug-fast', however, *Staphylococcus* lost this property rapidly in media not containing penicillin. The authors refer to work which showed, on the other hand, that pneumococcus type III, made resistant to penicillin, either by culture in media containing penicillin (G. Rake *et al.*, *J. Immunol.*, 48, 271, 1944) or by passage through mice treated with penicillin (L. H. Schmidt and C. L. Sesler, *Proc. Soc. Expt. Biol.*, N.Y., 52, 353, 1943), retained its resistance. The nature of these phenomena of resistance requires further investigation. Although some organisms can produce a penicillinase which destroys penicillin (see, for example, the penicillinase produced

by *B. subtilis* reported by E. S. Duthie, *Brit. J. Expt. Path.*, 25, 96, 1944), resistance to penicillin apparently does not always depend on the production by the resistant organism of penicillinase. W. M. Kirby (*Science*, 452, June 2, 1944) has extracted a substance which is not penicillinase from *Staphylococcus* resistant to penicillin. G. LAPAGE

INDIAN FOREST YIELD TABLES

EVER since the Forest Research Institute came into being at Dehra Dun (1907), the Sylvicultural Branch set out to obtain data for the preparation of volume and yield tables for some of the more important timbers such as teak, sal, and deodar, to mention but three of the best known throughout India. Selected sample plots of varying type and age had been previously formed by the forest officer in different parts of India, and more or less periodically measured and records kept. But for the most part the work was spasmodic and a proportion at least of the data obtained of doubtful usefulness.

As a result of the work inaugurated, attempts were made to prepare yield tables, among others, for the sal (*Shorea robusta*), such a table was prepared by Smythies and Howard and published in 1923. It was based on the measurements of some fifty-two plots of sal, chiefly in the United Provinces, with a few in Bengal and the Central Provinces. The sal has a wide distribution from the foothills and neighbouring border in the plains in the United Provinces as far west as the Jumna River, eastwards along this line through Nepal and Bengal Duars into Assam as far as Tezpur, its eastern boundary. To the south it is found in the eastern part of the Central Provinces and in Chota Nagpur, south-western Bengal, Orissa Province and Orissa Feudatory States to Ganjam in the Madras Provinces. It thus is equally at home in a dry hot as well as in a damp hot climate, and grows on a variety of soil conditions. Since the above tables were published, many more data have been collected, and this information has been collated in *Indian Forest Records* (Sylviculture) New Series, "Yield and Stand Tables for Sal (*Shorea robusta*) High Forest" (4A, No. 4, Model Press, Delhi, 1943) by M. L. Griffith, sylviculturist, and Bakhshi Sant Ram. The present tables are based on 542 measurements from 225 sample plots in twenty-five forest divisions of five provinces. Sample plot selection, upkeep and measurements in the different provinces are now greatly facilitated by the existence in the provinces of provincial sylvicultural research officers whose investigations and results are available to the Central Research Institute. That this departure is of the highest value is evidenced by the authors' remark, "The tables now produced are admittedly not completely satisfactory on account of the abnormality of some of the basic data. The main difficulties arose through inconsistent thinning procedure. These have been described in more detail together with the methods attempted to overcome them."

Just as the progress in ordered management of a forest department is indicated by the number of the forests which have been placed under working plans, including the type of plan in force, so the degree to which sylvicultural work has advanced is evidenced by the possibility of being able to prepare suitable yield and stand tables for use in the forests under management.

ADSORPTION OF WATER BY PROTEINS

IT is recognized that proteins contain two types of hydrophilic groups capable of binding water by hydrogen-bond formation, namely, polar side-chains such as those from lysine, glutamic acid, tyrosine, etc., and the oxygen and nitrogen associated with peptide bonds in the peptide chains. Adsorption curves are of the typical *S*-shape separable into three segments, the first part, at low pressures, characteristic of Langmuir adsorption, a second part with a more or less linear relation between adsorbed amount and vapour pressure, and a third part corresponding with a large increase of amount adsorbed with increase of vapour pressure.

H. B. Bull (*J. Amer. Chem. Soc.*, 66, 1499, 1944), who defines protein hydration as water released when moist protein in equilibrium with saturated water vapour at 25° or 40° is dried in vacuum for 24 hours at 105°, and calculates the free energy and heat changes in adsorption, concludes that the theory of multi-layer adsorption proposed by Brunauer, Emmett and Teller (*J. Amer. Chem. Soc.*, 60, 309, 1938) explains the results in a very satisfactory manner. This extends the Langmuir theory of mono-layer gaseous adsorption to the case where more than one layer of molecules are adsorbed, and the resulting curves were found to resemble those obtained in the experiments.

The results are believed to be consistent with the view that the protein molecules in the solid state are linked together to form coherent planes, the exposed surfaces of which are hydrophilic, and water is adsorbed between these planes. The final rise is thought to correspond with a saturation of exposed polar groups with water and the beginning of a process of solution of the protein. Heat coagulation of egg albumin seems to involve interaction between polar groups on neighbouring molecules, with a decrease in water-binding capacity.

It is thought that there is no direct relation between the amount of water held by a solid protein in a saturated atmosphere and the amount of water held by a protein when it is dissolved in water, the latter being mainly dependent on the total hydrophilic surface exposed to the water.

EFFECT OF MULCHING ON THE SOIL

MULCHING is a recognized method of conserving soil moisture, but often several other effects of the treatment are noticeable. This is not, of course, unexpected when the mulch consists of organic material containing soluble plant nutrients in greater or less amount.

I. W. Wander and J. H. Gourley¹ found that mulching with straw increased the contents of potassium, calcium, magnesium, phosphorus and boron in the soil, the effect being most marked for potassium, while H. Painter and G. F. Potter² report that with young tung trees mulching reduced signs of potassium deficiency, and C. E. Baker³ found a mulch as effective as dressings of muriate of potash in increasing the potassium content of apple and peach leaves. These results may not be due entirely to potassium supplied by the mulch, as C. E. Baker⁴

found that mulching with cinders or glass wool increased the potassium content of apple leaves, possibly because under the mulch a concentration of feeding roots near the soil surface, where potassium concentration is highest, occurred. Mulching with poor hay, also with apples, encouraged the production of surface feeding roots in addition to increasing soil moisture⁵.

The effects of mulching, however, are not always beneficial, and L. P. Latimer and A. P. Percival⁶ found that although hay or seaweed mulches, as compared with grass covering, increased growth and fruit sizes in apples, sawdust used as a mulch did not have this effect, but did increase fruit and decrease leaf colour, suggesting that it had induced a slight nitrogen deficiency. W. A. Johnson⁷, using sawdust as a surface mulch for tomatoes, found that it decreased the soil nitrate content slightly and when incorporated in the soil, as mulch materials usually are eventually, depressed the soil nitrate appreciably so that heavier nitrate applications were required. The sawdust conserved soil moisture and caused the soil to be less compact, but repeated sawdust mulches may have undesirable effects. L. M. Turk and N. L. Partridge⁸ found peat unsatisfactory as a mulch as it prevented light rain from reaching the soil, while loss by evaporation from the mulch continued. These ill-effects were not found when the mulch used allowed free percolation of water, and gravel, straw and sawdust were all effective in this respect.

FORTHCOMING EVENTS

Wednesday, April 4

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W. 1), at 5 p.m.—Mr. F. J. Macdonald "The Freezing Point of Sour Milk"; Dr. H. Liebmann and Mr. A. D. Ayres "The Electrometric Determination of Ascorbic Acid"; Mr. H. W. Webb "Magnetic Stirring in the Electro-Deposition of Metals".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (joint meeting with the TELEVISION SOCIETY) (at Savoy Place, Victoria Embankment, London, W. C. 2), at 5.30 p.m.—Mr. D. C. Birkinshaw and Mr. D. R. Campbell "Studio Technique in Television".

Thursday, April 5

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W. C. 2), at 5.30 p.m.—Mr. L. J. C. Connell, Mr. O. W. Humphreys and Mr. J. L. Rycroft "The Place of Radiant, Dielectric and Eddy Current Heating in the Process Heating Field".

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S. W. 1), at 6.30 p.m.—Dr. A. G. Pugsley "Modern Experimental Work on Aeroplane Structures".

Friday, April 6

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION) (at Savoy Place, Victoria Embankment, London, W. C. 2), at 5.30 p.m.—Discussion on "Are Engineers Losing their Sense of Proportion on the Accuracy of Industrial Measurements?" (to be opened by Mr. H. D. Hawkes).

INSTITUTE OF PHYSICS (SCOTTISH BRANCH) (in the Natural Philosophy Department, The University, Glasgow), at 7.30 p.m.—Dr. W. Hume-Rothery, F. R. S. "The Theoretical Interpretation of Alloy Structures".

Thursday, April 5—Monday, April 9

BRITISH PSYCHOLOGICAL SOCIETY (at the University College of the South West, Exeter)

Friday, April 6

At 9 30 a.m.—W. D. Furneaux "An Experimental Study of Suggestibility and Hypnosis", Wm. Fred Raphael "Surveys of Employee Attitude". At 11 20 a.m.—Hilda Lewinsky "Psychological Aspects of Cooking for Oneself", W. D. Wall "Reading Backwardness in the Army". At 5 p.m.—Margaret Lowenfeld "The Mosaic Test"

Saturday, April 7

At 9 30 a.m.—Discussion on "Psychological Implications of Culture Patterns" (Prof. T. H. Pear, Dr. A. I. Richards and other speakers). At 5 p.m.—Dr. Millais Culpin Presidential Address. At 8 30 p.m.—Display of Instructional Films arranged by the Visual Education Centre, University College, Exeter

Sunday, April 8

At 2 30 p.m.—An Account of the Work of the Devon Committee for Education in Mental Health and of the Committee of Professional Psychologists (Mental Health) of the British Psychological Society. At 5 p.m.—M. D. Vernon "Perception and Understanding of Graphical Material", Charles Burns "Types of Problem Children". At 8 30 p.m.—Alec Rodger "The Work of the Admiralty Psychologists", G. Patrick Meredith "The Problems and Methods of Visual Education"

Monday, April 9

At 9 30 a.m.—Eric Farmer "Problems in the Occupational Adjustment of the Blind", M. I. Dunsdon "The Binet Test as adapted for the Blind". At 11 20 a.m.—I. Langan "Demonstration of Binet Tests for Blind Children". At 11 50 a.m.—M. B. Stott "Some Differences between Boys and Girls in Vocational Guidance". At 5 p.m.—Dr. K. I. W. Craik "Refractory Period in Sensory-motor Action", H. Himmelweit "Level of Aspiration, as related to Neurosis and Temperament". At 8 30 p.m.—Open Session for Discussion

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

DEPUTY BOROUGH ELECTRICAL ENGINEER AND MANAGER to the Borough of Barking—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. D 1048 XA) (April 9)

GRADUATE TEACHER OF MECHANICAL OR ELECTRICAL ENGINEERING in the Southend Municipal College—The Chief Education Officer Education Office, Warrior Square, Southend-on-Sea (April 10)

PATENT AGENT, preferably specializing in ELECTRONICS, as Assistant in Patent Department—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3127 XA) (April 11)

MECHANICAL ENGINEER (fully qualified), in N.W. Area, by Engineering Company designing and constructing Electricity Generating Stations and Industrial Plants—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. C 2512 XA) (April 12)

GRADUATE ASSISTANT LECTURER in the MECHANICAL ENGINEERING DEPARTMENT in the Coventry Technical College—The Director of Education, Council House, Coventry (April 16)

ASSISTANT LECTURER AND DEMONSTRATOR IN BOTANY—The Principal, Royal Holloway College, Englefield Green, Surrey (April 21)

LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY—The Secretary and Registrar, The University, Bristol (April 23)

ORGANIC CHEMIST in the RESEARCH DEPARTMENT of a well-known firm in the London area, to carry out experimental work leading to the formulation of protective and decorative coatings for sheet-metal containers—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 2719 XA) (April 26)

MECHANICAL AND ELECTRICAL ENGINEERS by the Gold Coast Government Public Works Department—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. C 2526 A) (April 28)

CHAIR OF PHILOSOPHY in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (April 28)

CHIEF ANALYTICAL CHEMIST in the RESEARCH DEPARTMENT of a well-known firm in the London area—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3073 XA) (April 28)

ASSISTANT SECRETARY to the INSTITUTE OF PHYSICS—The Secretary, Institute of Physics, c/o The University, Reading, Berks (April 28)

LECTURER IN ELECTRICAL ENGINEERING—The Registrar, The University, Sheffield (April 30)

METALLURGIST for a position in the RESEARCH DEPARTMENT of a large firm in Yorkshire—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 2721 XA) (April 30)

KEEPER OF THE DEPARTMENT OF ZOOLOGY—The Director, Museum and Art Gallery, New Walk, Leicester (April 30)

METALLURGIST for a position in the RESEARCH DEPARTMENT of a large firm in South Wales—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 2720 XA) (May 12)

PROFESSORSHIP OF MECHANICAL ENGINEERING—The Principal, Heriot-Watt College, Edinburgh (May 14)

UNIVERSITY CHAIR OF CHEMISTRY tenable at King's College—The Registrar, University of London, c/o Richmond College, Richmond, Surrey (May 18)

READERSHIP IN HUMAN PHYSIOLOGY—The Registrar, University Registry, Oxford (June 16)

KEEPER OF THE DEPARTMENT OF ART—The Director, National Museum of Wales, Cardiff (June 30)

GEOLOGIST to the Government of Trinidad to co-ordinate geological information, compile geological map after necessary surveys and advise on geological questions connected with petroleum industry development in the Colony—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3769 A) (August 31)

MECHANICAL INSPECTOR OF WORKS (temporary) by the Government of Sierra Leone for the Electricity Branch of the Public Works Department—The Ministry of Labour and National Service, Appointments Department, A 3(A), Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. O S 605)

EDITORIAL ASSISTANT by British Council to help in production of a monthly journal published in several languages—The Ministry of Labour and National Service, Appointments Department, A 3(A), Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. P Q 144)

DIRECTOR OF THE CITY OF LONDON COLLEGE—The Secretary, City of London College, Electra House, Moorgate, London, E.C.2

INTERDEPARTMENTAL CO-OPERATION IN RESEARCH

AN account of what is being done in America in the broad field of experimental human biology to promote co-operative research has been given in a recent paper on "General Aspects of Interdisciplinary Research in Experimental Human Biology" by Dr. Josef Brozek and Prof. Ancel Keys, of the University of Minnesota (*Science*, 100, 507, 1944). This paper, apart from its specialized interest, is of wide importance in that it indicates some of the fundamental problems of the most effective organization of research effort everywhere, and it is a valuable contribution to constructive thought on the unity of knowledge. It will be recalled that the Manchester Literary and Philosophical Society recently devoted a meeting to this subject, and to the means of redressing that progressive disintegration which, as Prof T W Manson emphasized, is such a characteristic feature of our civilization.

Dr. Brozek and Prof. Keys direct attention to some of the implications of the attempt to develop in the academic field the co-operative attack on problems by whole groups of specialists such as physicists, biochemists, bacteriologists, nutritionists, pathologists, physiologists, histologists, and psychologists. At present, competition between university departments may create a barrier to interdepartmental work. Again, it is pointed out by Dr M A. May, director of the Yale Institute of Human Relations, that the departmental method tends to encourage individualism and to discourage the ambitious worker from participating in interdepartmental collaborative projects. A third barrier is formed by traditional attitudes and ideas, such as the belief that scientific discoveries are always the products of individual minds, or that the co-operative setting limits the freedom of the scientific worker to follow the dictates of his own intellectual curiosity. A fourth barrier results from university training in habits of individual work.

As a result, Dr Brozek and Prof Keys point out, the young scientific worker is poorly prepared to participate in the activities of a committee or a research team. He may have become skilful in gathering empirical data within his own narrow field, but his techniques of social interaction are undeveloped and ineffective in practice. The Yale Institute of Human Relations was created more than a decade ago to meet this need for bridging several anthropological disciplines. The purpose was to correlate knowledge and co-ordinate technique in related fields, so that greater progress may be made in the understanding of human life from the biological, psychological and sociological points of view. Since 1930 other university institutes have been organized on inter-disciplinary lines, and Dr Brozek and Prof. Keys strongly urge that such developments should form a part of graduate schools and not be left to industrial organizations, which will rarely provide the time and personnel to carry out a training programme of high scientific standing.

There can be little doubt that Dr Brozek and Prof Keys are on firm ground in urging that more should be done to break down departmentalism and encourage the attack on fundamental problems by workers in different branches of science. That idea was clearly present in the discussions at the recent British Association Conference on Science and Industry, but industrial experience as a whole scarcely suggests that the average research worker finds it as difficult to fit into an interdisciplinary team as the present paper implies. Both the competitive and co-operative habits can be encouraged in the process of learning, but much also depends on the personality of the individual worker.

The real case for stimulating supervision of the type here suggested, with its consciousness of scientific and social responsibilities, is the spur it gives to creative thought at the borderline of the sciences concerned. That as well as the encouragement of habits of co-operation and understanding is the outcome of broadening the background of the student and integrating the discipline he primarily follows more closely with the field of knowledge as a whole. Dr Brozek and Prof Keys rightly point to the value in this respect of a course in the philosophy of science, and they stress particularly the importance of including the theory of meaning and the study of verbal and non-verbal symbols used in representing scientific concepts and their combinations, the logic of the scientific method which deals with experimental design, collection of data, analysis of the error of measurement, process of inference and testing of hypothesis, and the concrete logic or systematology of the sciences based on analysis of their subject-matter and methods used.

Much of course would depend on the way in which such philosophy is taught, but beyond this, stress is laid on the necessity of working facilities for getting acquainted with the problems and methods of neighbouring fields, and familiarity with current problems. These, in fact, rather than the development of social skills, are the essential factors for stimulating an effective scientific co-operation, but in actual practice the methods and organization developed at the Laboratory of Physiological Hygiene at the University of Minnesota do not appear to overstress the third factor, and they provide ample encouragement for individual initiative and personal responsibility. It is worth recalling that something of the same kind of plea for the teaching of philosophy was voiced in respect of engineering at a Conference on Industry and University Education held last December in London by the Vacation Work Committee of the Imperial College of Science and Technology (see *Nature*, March 31, p. 402), and the article on "The Churches and European Reconstruction" which the Bishop of Chichester contributed to a recent number of the *Contemporary Review* is important for the same emphasis that is laid on the need for a spiritual unifying force, to be found not merely in science, which will restore hope and purpose.

This emphasis on the importance of the unity of knowledge is to be found in other discussions which

have centred around the universities and their functions in the modern world. Prof Manson's address, referred to above, was largely concerned with the part which the universities might play in restoring a measure of unity to civilization if they set their own house in order by clearing themselves of the charge which the late Archbishop of Canterbury once levelled against them in a sermon before the University of Oxford, that a university "is a place where a multitude of studies are conducted, with no relationship between them except those of simultaneity and juxtaposition". That is a problem which must be frankly faced in dealing with the reconstruction and expansion of the universities. It is germane to the fundamental questions as to the functions of the universities and their place in the society of to-day, and was indeed frankly faced by both Dr Lowe in "The Universities in Transformation" and by F. R. Leavis in "Education and the University".

More recently, the whole question has been very concisely but admirably discussed by Prof. John Macmurray in his article "The Functions of a University" in the *Political Quarterly*. Prof. Macmurray, stressing the cultural function of a university as the key to its functions of research and of teaching, urges that the life of a university should be effectively bound up with that of society about it. This cultural function cannot be fulfilled decisively unless the university is a place where knowledge is unified and not merely a common house for disjointed specialisms, and unless this unification is in constant and vital relation to the cultural life in the community around the university. A university must be designed to encourage and facilitate the interchange of knowledge through which it can become a spiritual whole, but the departments of knowledge can only be unified in the active life of a human community.

It is in this cultural function that our universities are most conspicuously failing, and that is essentially the point of Mr A. S. Nash's criticism in his more recent book "The University in the Modern World". Prof. Macmurray lays the responsibility for this failure rather on the disintegration of traditional culture than on the universities themselves, and although he makes no suggestions as to how these three functions can be effectively discharged under modern conditions, he looks forward with some confidence. The use of science for social ends demands a unity of purpose in society which must express itself in, and depend upon, the achievement of a cultural synthesis. Changes in social structure and social outlook are taking place which will alter the demands made upon all our educational and cultural institutions, and Prof. Macmurray looks to a period of social and cultural unification. His paper, no less than that of Dr. Brozek and Prof. Keys, is a challenge to the critical and constructive thinking on the ultimate functions of the university and its place in modern society which must precede the adaptation and re-organization of its structure and methods, so as to serve these aims and functions more effectively in the new age.

A LANDMARK IN ALGOLOGY

The Structure and Reproduction of the Algae

By Prof F E Fritsch, Vol 2 Foreword, Phaeophyceae, Rhodophyceae, Myxophyceae Pp xiv + 939 (Cambridge At the University Press, 1945) 50s net

WITH the publication of this volume the whole botanical world, and algologists in particular, owe a special debt of gratitude to Prof Fritsch. Although ten years have elapsed since the appearance of the first volume, it is no mean achievement under present conditions to have produced this companion work, and both Prof Fritsch and the Cambridge University Press are to be congratulated on their courage and determination.

The two volumes virtually represent Oltmann's brought up to date and greatly expanded, and they will undoubtedly form the algologist's *vade mecum* for many years to come. Considerable advances have been made since the last edition of Oltmann's was published, and a new work, preferably in the English language, was plainly demanded. The labour involved in the preparation and execution of such a task is enormous, and Prof. Fritsch can look back with every satisfaction upon his handiwork. This and the companion volume alone would ensure him the immortality of the earlier great algologists.

The real reward for producing such a book must ultimately lie not only in the stimulus it gives to research but also in its influence in directing future research. This second volume should exert a profound effect upon both. The publication of such a book is obviously the moment to reflect upon the present position of algology. It is clear that in recent years the principal advances in the morphology of the brown algae have been mainly in certain groups, for example, Fucales, Ectocarpales, whereas in others, for example, Laminariales, there has been little further progress. In the Rhodophyceae the extensive work of Kylin and other Scandinavians has opened up much that was unknown, the frequent use of Kylin's figures being eloquent testimony of his contributions. In reading the present volume one cannot but be impressed by the extensive advances in knowledge, but at the same time the remaining lacunae obtrude upon our notice. In general, more work is needed, especially by those favourably placed, upon tropical and southern hemisphere genera. In particular, *Apakpus*, *Arthrocladia*, *Adenocystis*, *Dictyotopsis* and *Padina* among the Phaeophyceae need further study, the Encelaceae, Tilopteridales and extra-European Sporocnales have many secrets still to yield, and cytological investigation is sorely required in *Soranthera*, *Ascocyclus*, *Ectocarpus Lebelii* and *Sphacelaria*. Similarly in the Rhodophyceae, outstanding problems could be assisted by a study of the development of *Delesseria* and *Nitopyllum*, and by investigations of the genus *Compsopogon*, the Sarcomenae and the parasitic Florideae as a whole. The cytology of *Galaxaura* and the Gelidiales is practically untouched, and the absence of female plants in *Rhodymenia palmata* and *Halosaccoramentaceum* is no mean problem. In the Myxophyceae, the Entophysalidaceae and Pleurocapsales are most in need of attention. The above are just a few of the lacunae that need to be filled.

The concept of heterotrichy, one of Prof. Fritsch's greatest personal contributions to algology, pervades the volume, and for the first time one can see it in

full perspective. Here one regrets that Prof Fritsch's four recent studies in comparative algal morphology were not included in this volume, because they form a summary of the valuable material contained in this book. It is still painfully evident that we are no nearer solving the puzzle of the origin of the Phaeophyceae and Rhodophyceae. On the other hand, recent cytological work suggests that we might well abandon the old concept of alternation of generations and refer rather to alternation of phases (*v* Drew, *Ann. Bot., Lond.*, NS 7, 23, 1943). In this connexion one feels that the term triplobiont might well have been introduced, as indeed it has been by Drew, to cover those cases among the Rhodophyceae with a triploid phase. Thus the statement on page 415 that the remaining Rhodophyceae are diplobiontic is somewhat misleading.

I am not certain that the fundamental change of arrangement adopted for the treatment of the Rhodophyceae is advantageous, because in some cases members of the same family (for example, Corallinales) are treated pages apart. This, however, is not necessarily an opinion that will be shared by others.

It is a vain hope these days for authors not to expect their books to become out of date in minor details almost before they are published. Thus, the freshwater Phaeophyceae are no longer restricted to the Ectocarpales, for in 1943 a freshwater member of the Sphacelariales was reported from China, while in the same year David published an important contribution on the growth and ecology of *Ascophyllum*.

For most research workers the intrinsic value of this book will lie in the magnificent collection of references to the extensive literature. Here everyone will acknowledge the great debt we owe to Prof Fritsch. The author says that the section on ecology is not exhaustive, but at the same time one would have liked to see some reference to Bokenham's work on algal recolonization, and also to the splendid series of biotic studies of the South African intertidal zone by Stephenson and his co-workers, whose results are independent of those of Isaac. In the section on salt marsh fucoids, there is no reference to two relevant papers on American salt marsh algae. In other parts of the book the important review paper by Hoffmann on the utilization of seaweeds is missing, and there is also more recent literature than that quoted on alginic acid and agar. Morphologically, the principal omission is the important work of Kirjeva and Shapora on growth and reproduction of *Laminaria* in Kola Fiord, while the work of Zimova on the same genus is also not mentioned. In the genus *Dictyota*, Collins, as well as Holden, has recorded the presence of antheridia and tetraspores on the same plants in one species, *D. indica*, the tetraspores not undergoing normal division.

In a work of this magnitude it is inevitable that small points should be overlooked, but this reflects no discredit on the author; rather the reverse because, although the field is so vast, the omissions are almost negligible. However, one would like to have seen some reference to the morphology of those interesting endophytes, *Schmatzella mirabilis* and *Rhodochorton endozoicum*. Some reference might also have been desirable to the three physiological races of *Laminaria cloustoni* described by Montfort, further, there is no mention of the galls caused by the nematode *Tylenchus fucicola* on *Ascophyllum* and *Desmarestia*, although there is a reference to similar galls in the Rhodophyceae. Mention is made of the use of brown algae for the

manufacture of potash, but this industry really commenced with the use of the Fuci as a source of soda for glass and glazing. *Rhodymena palmata* with 0.7 per cent iodine contains more than *Trachella*, while *Phyllophora nervosa* is so rich in this element that the Russians use it as a commercial source of iodine. Some of the algae are also richer in protein than is indicated, for example, *Porphyra tenera* (28 per cent) and *Undaria pinnatifida* (11 per cent).

The great care expended by Prof. Fritsch on this work is seen in the almost entire lack of printing errors. The most important of these are several references to Maps 1 and 2, said respectively to be on pp. 8 and 250, whereas both are at the end of the volume. The footnote on the reproduction of *Hildenbrandia rivularis* is somewhat confusing, and in conjunction with the text leads one to think that the genus has no reproductive organs. Nearly all the numerous illustrations are of excellent quality, but it is evident that some, for example, Figs. 6 D, 36 A, 91 G, 199 H and 289 E have suffered severely in reduction, and the photographs, Figs. 64 and 117 B, also are not very clear.

All these points, however, are but minor details in a volume that is of first-class importance. Its production has restored the prestige of English algology built up by the workers of the last century. It is a volume that all who can afford it should possess, and no library should be without it. The Cambridge University Press is also entitled to congratulations on producing such a well-constructed book in wartime.

V. J. CHAPMAN

TWO FARMERS LOOK BACK

Farming Memoirs of a West Country Yeoman
By S. G. Kendall. Pp. 247. (London: Faber and Faber, Ltd., 1944.) 12s. 6d. net.

Thirty Years Farming on the Clifton Park System
How to Supply Humus, Texture and Fertility by the aid of Deep-Rooting Grasses. By William Lamm. Pp. 110+3 plates. (London: Faber and Faber, Ltd., 1944.) 7s. 6d. net.

ANYONE who knows an English village well knows that there is usually someone with a gift for telling a story, developed perhaps in the friendly atmosphere of the 'farmers' ordinary', or even in the alehouse or in the camaraderie of farm work. Some combine this with another gift, the ability to put the story into writing. In recent years there have been many discoveries of these talented people, and they have been encouraged to write down what they have to say. Messrs. Faber and Faber have been particularly successful in finding some of these men and they have recently issued several books, each a first effort, by a farmer whose story would otherwise never have got beyond his own village.

One of the latest is the "Farming Memoirs of a West Country Yeoman" by S. G. Kendall. It is in many ways a remarkable production. Mr. Kendall has been farming all his life near Bath, as his father and grandfather had done before him. He is now nearly eighty-six, so that the joint lives of all three stretch over a considerable period. He begins his book with an account of the disastrously wet harvest of 1860, when the grain sprouted badly in the stook and the flour yielded a dough which would neither rise nor bake properly, so that the inside of the loaf was stodgy and sticky with a sickly, sweet, un-

palatable flavour. Two knives had to be used, one for the actual cutting, the other to clean the first knife before it would cut again. But the housewives of those days were very ingenious: they met the difficulty by leaching wood ashes with boiling water, allowing the insoluble material to settle, and taking off the clear liquid (which was mainly a solution of potassium carbonate) and using it for making the dough. The improvement was considerable, though the result was still not entirely satisfactory.

In those early days the main products of a Wiltshire farm were sheep and corn. The dairy cows were let to a dairyman at a certain price per head per annum; he tended them, made butter or cheddar cheese, in addition, he could keep as many pigs as the accommodation permitted. The farmer replaced any cows that died and provided some of the milkmen.

Agriculturists will read with interest the author's short summaries of the various seasons. 1874 was the peak of success: yields of corn were good, prices were "fairly remunerative", while values of beef, mutton, milk, butter and cheese all steadily increased—the result, in his view, of the Franco-German war. A considerable amount of labour was needed, but it was always forthcoming, the men worked well and willingly. Hours were very long: work in harvest time began at 3 a.m. and went on until dusk; wages were low—13s.—15s. a week—families were often large, and at the end of a strenuous life the workers could look forward only to the workhouse, or, if they wished to stay outside, to a Poor Law pension of 2s. 6d.—4s. a week with or without a loaf of bread. During their working lives there were, of course, compensations: Harvest Homes, Christmas feasts, fairs, etc., and clearly the workers enjoyed life, but undeniably it was very hard. Their diet must have been good, for they were very strong.

The year 1877 was not a bad season; wheat sold at £3 per quarter. The worst season of the nineteenth century was 1879 by reason of its cold, wet summer and harvest, and in the following season, 1880, there were considerable sheep troubles. 1881 was better so far as yields and quality were concerned, but prices were falling; by 1886 the combination of bad seasons and low prices had forced many farmers out of business and many farms were derelict. 1891 and 1892 were both difficult years, 1893 was second only to 1879 for utter badness, but this time it was from excessive drought—a most unusual cause for low yields of grain. To make matters worse, prices collapsed—the result of a financial crisis in the western States—and the miserable yields of wheat sold for only 23s. a quarter, sheep and lamb prices were also low. Things improved later, and Mr. Kendall was able to keep going.

The agricultural details, however, are only part of the interest of the book. It is a very human document, and Mr. Kendall has a keen eye for the beauty of the countryside and a very lively interest in the doings of country people. So he gives accounts of feasts and weddings, of dances, skating and political meetings in barns, of exciting rescues of cattle from a disastrous flood and of sheep from a severe snow storm, and of other events—all written in a vivid, sometimes eloquent, style and interspersed with a wide range of quotations from "Alice", Southey, Burns, Charles Kingsley and others. He modestly does not publish photographs of himself, but we can perhaps picture him as the modern counterpart of another but much earlier nineteenth-century farmer also a great reader of poetry with an eye for the

beauties of Nature—Mrs Gaskell's "Thomas Holbrook". The general reader will enjoy the book as much as the agriculturist

Mr Lamin's book is altogether different in character. It is written for farmers by a farmer, though its scope is a good deal wider than the title indicates. He also is well over eighty years old, he writes clearly and he has a good story to tell. The son of a farmer, he worked on his father's farm near Nottingham until he was twenty-four, when his father set him up as a butcher. 'But the call of the land was too strong, and after five years he took the farm next to his father's a poor, run-out sandy stretch, its soil liable to be blown away in a high wind, washed away in high rain, or scorched on a hot day. It had been unlet for nineteen years. He struggled on for five or six years, then came across Mr R. H. Elliot's book describing the system followed at Clifton Park. This book made a great stir in its day, and it is still useful now. Messrs Faber and Faber have, in fact, re-issued it. Like other agriculturists of his time, Mr. Elliot did not think the sub-soil on his land was adequately treated, and in his seeds mixture he included some deep-rooting plants that would open it up. The idea appealed very much to Mr Lamin, and he thought that if he could get enough fibrous root material into the surface and the subsoil of his farm he would not only fix the soil but so enrich it in humus that he would greatly increase its productiveness. So he evolved a seeds mixture on Elliot's lines including cocksfoot, meadow fescue, rough-stalked meadow grass, Montgomery red, Aberystwyth white and Kentish white clovers; chicory, burnet, yarrow and sheep's parsley. This was left down for four years and each year gave excellent crops, finally leaving the soil enriched with a good turf and a mass of deep roots that not only stopped the loss by blowing away and washing, but also made an admirable foundation for the succeeding crops. oats, potatoes, silage crops, etc. He would not, however, include rye grass in his mixtures.

Mr Lamin used artificial fertilizers liberally, and has some rather scathing things to say about those who claim that they are ineffective or even harmful.

The book contains a great number of practical details of considerable agronomic interest and not easily accessible elsewhere, and it records an achievement of which Mr. Lamin may well be proud.

E. JOHN RUSSELL

THE COUNTRY TOWN

Country Towns in the Future England

A Report of the Conference representing Local Authorities, Arts and Amenities Organizations and Members of the Town and Country Planning Association on the 23rd of October, 1943. Edited by Stanley Baron. Pp 140 (London: Faber and Faber, 1944) 8s 6d. net.

THE main title of this book is somewhat of a misnomer. The book is a straightforward report of a conference held in the autumn of 1943 under the auspices of the Town and Country Planning Association, at which representatives of some ten per cent of the smaller towns of England were told how to plan to get more industry and better amenities into their boroughs. Short speeches were made by representatives of five of the towns themselves: a health resort (Malvern), a garrison town (Richmond,

Yorks), an agricultural centre (Wisbech), a 'one-industry' weaving town (Haslingden) and a moribund ancient borough (Brackley). Conditions were very different, but all advocated the same solution—new light industries.

It was left for Prof Ashby, in opening a discussion, to make much the most important contribution to the conference and to this book. He carefully analysed the reforms that the small country towns must undertake before they can become attractive habitats for the staffs of decentralized industry. He also reminded the conference that in the last resort the economic welfare of the country town is dependent on the well-being of its surrounding agricultural and village communities. The primary requirements of a country town are suitable facilities for marketing agricultural produce, adequate transport arrangements for goods and passengers, a full range of supply services in agricultural requirements, a choice of banking services, a full range of supply of retail shopping facilities; a choice of good repair and maintenance garages; an adequate supply of cafés and restaurants, an adequate supply of hotels, as well as of public houses; at least one good cinema; and provision for technical education. The smallest town able to provide these requirements in full would have at least 7,000 inhabitants, and more often 10,000.

The course of action that should be followed by country towns which wish to attract industry was outlined by Mr. R. L. Reiss, deputy chairman of Welwyn Garden City, and Mr. T. A. L. Paton. They put forward the following desiderata: grouping of factories to spread costs of public utility services, good road communications, building sites at least 200 ft deep and 100 ft. wide, the building line set back 25 ft. from a 50-ft road, railway sidings for a few larger factories, which must have sites at least 700 ft deep, single-story factories built to rent, each with a 40-ft frontage and depths varying from 65 ft. to 100 ft., building to cover only 20 per cent of the total area of the industrial estate when fully developed in order to leave sufficient elasticity for necessary expansions and avoid the creation of a factory slum. Pre-war development costs were £800–£2,000 an acre before the first brick of a factory was laid.

The third session was devoted to amenities and was addressed by Miss Glasgow, secretary of the Council for the Encouragement of Music and the Arts. She said that places of about 30,000 population should be able to support a theatre seating 700–800, a concert hall, a library, an exhibition gallery and several cinemas. In towns of some 20,000, the theatre would probably also have to serve as a concert hall and public meeting place, and might well have an exhibition gallery as an annexe. With less than 10,000 people, townships could only support a community centre, this should not consist of one elaborately equipped hall, but of a group of smallish rooms to form a library, an art room, a little theatre and a music room.

In the book these constructive suggestions are surrounded by much general discussion, but the whole makes interesting reading, and (together with the National Council of Social Service report "Dispersal") is a useful corrective to the view that the re-location of industry can be settled by engineers, based on the suitability of each site from considerations of raw materials, transport and markets.

J. TYRWHITT.

NATURAL HISTORY OF GRANITE

By PROF. ARTHUR HOLMES, F.R.S.

FOR a century and a half the origin of granite (including granodiorite) has remained one of the most intractable and controversial of the problems geologists have tried to solve. Fouqué and Levy's comment in 1882, that "it excites the most lively discussion", is as true to-day as ever before, and indeed might be regarded in some countries as a mild understatement of the passions that are aroused by apparent conflicts of evidence and very real conflicts of opinion. Hutton clearly established the status of granite as a crystalline plutonic rock, but the French geologists and Lyell and his followers soon realized that not all granites are necessarily of igneous origin. Some occurrences were seen to have no sharp contact against the aureole of metamorphic rocks, but to merge into the surrounding schists through a transitional zone of gneisses and feldspathized schists so gradually that at no point could it be said that the rock ceased to be metamorphic and became igneous. These granites consequently came to be regarded, not as representing the cause of metamorphism, but as being the extreme products of its action.

Discussion thus became focused on the question whether a given mass of granite had crystallized from an intrusive magma which mechanically displaced the pre-existing rocks, or whether the granite had been made out of the pre-existing rocks by some process of ultra-metamorphism which was thought to culminate locally in actual fusion. The extreme magmatists have since come to admit that magma may react with the invaded rocks and assimilate the products, while adherents of the metamorphic view have realized that chemical changes are essential for the formation of granite, and that the pre-existing rocks must therefore have been permeated by granite magma or its derivatives (including the *ichor* of Sederholm and the hydrothermal solutions favoured in America), or by more tenuous migrating materials of unspecified origin, referred to as mineralizing agents or emanations. Between these limits of interpretation, many grades of opinion have been held, especially as regards the origin of granite magmas. Those who insist that all granites are igneous accept granite magma as having been available, either in its own right or, more recently, as a residual magma thought to have been derived by fractional crystallization from an antecedent basaltic magma. Those who regard granites as having been largely formed from the pre-existing rocks recognize that they passed through a stage when part of the material was mobile or fluid. The partially fluid mash has been styled *magma* by Reinhard, to distinguish it from a mash consisting of incompletely crystallized magma. Moreover, magma may be generated from magma either by the attainment of complete fluidity or, at any stage, by the squeezing out of the fluid portion.

It is unfortunately not generally realized that the battle between rival camps has been repeated more than once, with varying fortunes at different times and in different countries. Most of the older English-speaking petrologists of to-day were brought up, like myself, in the faith that granite, being by definition an igneous rock, must have crystallized from a magma; and many of us have had to rediscover for ourselves that the plutonic characters of granite are not in themselves a guarantee of igneous origin. A fact, long overlooked, to which Scheerer had already

specifically directed attention so early as 1847. Still worse, we were left in ignorance of the stimulating ideas of the French school, or with the impression that they were old-fashioned and unworthy of serious consideration. Looking back, it is obvious that a carefully balanced historical introduction would have dispersed the fog of dogma and prejudice in which we were unconsciously groping. But no one had undertaken the arduous task of preparing such a survey, and in its absence enlightenment was slow and largely dependent on the luck of one's personal experience in the field. Iddings¹, it is true, had published a historical review of the origin of igneous rocks in 1892, but this dealt mainly with volcanic rocks and their magmas, and neither the problems associated with granite nor the achievements of the French school were as much as mentioned. Now, half a century later, full amends have been made to the masters of the past in two illuminating presidential addresses delivered by Prof. H. H. Read² to the Geologists' Association, the keynote being Hutton's remark "I have been particularly anxious about this subject of granite". Fortunately, our historian has a background of field experience that ensures sympathetic and competent judgments. Inevitably he holds up the mirror to himself as well as to others, but only to reveal himself as a good-humoured guide who neither claims authority nor acknowledges any, save only in the rocks themselves.

One of the 'high lights' of the story is the record of the great contributions made by the French, a record which anticipates in the most remarkable way the more detailed developments of recent years. In 1824 we find Ami Boué describing what would now be called granitization, and suggesting that the passage through crystalline schists of heat and gaseous exudations from the earth's interior was responsible for the growth of veins and disseminated crystals, and eventually for "a kind of igneous liquefaction". In 1837-38 Fournet distinguishes metamorphic rocks due to simple recrystallization from others in which partial melting has occurred, combined on occasion with inward and outward migrations of material. In 1841 Deville introduces the idea of mineralizing agents—gases which carry mineral matter and so chemically transform (as we should now say, by metasomatism) the rock substances through which they diffuse. In 1844 Virlet d'Aoust uses the term *imbibition* to express the idea that igneous materials have soaked into metamorphosed sedimentary rocks and transformed them into granite. Shortly afterwards, in 1847, he speaks of the process as *granitification*. In the same year, Fournet notes that, in certain metamorphosed sediments, far more felspar has developed than could possibly be accounted for by simple recrystallization, and so provides evidence that introduction of material must have taken place. In 1869 Delesse submits the hypothesis that granitized plutonic rocks may become so mobile that they can be squeezed towards the surface, to form intrusive granites at high levels in the crust, where they may have lost all the characters from which their true origin could be determined.

Before considering one of the major turning points in the history of petrogenesis which was now approaching, it is of interest to see what was happening in the British Isles during the rise of the French school. Following Lyell's suggestion, 'metamorphic' granites had been widely claimed in Scotland and Ireland, but more stress was given to heat and fusion, partial

or complete, than to change of composition and fluxing by introduced materials. In 1862 Scott and Haughton advocated a twofold origin for the granitic rocks of Donegal, of which they recognized both metamorphic and intrusive varieties. In 1871 Green³ described the vestiges of bedding that visibly remain in the granite of the Errigal district, and suggested that in places these ghost-like structures had been destroyed by fusion, and that the fused material, in virtue of its superior mobility, had behaved intrusively. The objection that in order to convert sedimentary rocks into granite certain missing substances would have to be restored was apparently not realized. A few years later this difficulty was independently faced by Clifton Ward (1876) on lines that the French work should already have made familiar. Discussing the origin of the granites of the Lake District, he writes: "Although a simple melting down might never produce granite, yet a moist fusion, accompanied by elementary substances, brought upwards from still greater depths, might effect a great transformation." Ward's suggestion was stillborn, and the old ideas lingered on in Ireland until adverse criticism from Callaway⁴ and Bonney, whose sympathies were with Rosenbusch, finally banished 'metamorphic' granite from the pages of the memoirs of the Irish Survey.

The critical year appears to have been 1877, when Rosenbusch⁵ published his classic work on the contact metamorphism of the slates around the granite of Barr-Andlau (Vosges) and showed by a series of chemical analyses that there was no significant change of composition in the altered rocks as they were traced towards the margin of the granite. Having found in this example no evidence of transfer of material into the country rocks, Rosenbusch afterwards denied the very possibility of such permeation, and claimed that the gneisses and feldspathized schists which elsewhere appeared to demand introduction of granite-making substances were themselves merely granites that had suffered dynamic metamorphism during orogenic movements. Like Werner, Rosenbusch attracted from abroad many students who afterwards achieved fame, and so great was his authority—outside France—that his doctrines dominated petrological opinion for two generations.

The French, however, did not allow their case to go by default. Barrois (Rostrenon, 1884), Michel Levy (Flammanville, 1893), and Lacroix (Pyrenees, 1898–1900) found large, well-shaped crystals of orthoclase, identical with those of the adjoining porphyritic granite, not only in the sedimentary schists outside the granite, but also in enclaves of similar material occurring within the granite. Neither the feldspars nor the granites show any sign of dynamic metamorphism, and the structures are entirely different from those of, say, the Mont Blanc granite, which has demonstrably been sheared. The crucial nature of the evidence provided by the 'big feldspars' has long been realized, since no one has seriously doubted that they must all have shared a common origin. Either they grew in solid rock or they crystallized from a magma. Identical feldspars could not be assumed to have originated in two entirely different physico-chemical environments. Those who believed that they could form only by crystallization from a magma resorted to various expedients to avoid the disturbing implications of their presence in contact zones and enclaves. Rosenbusch stubbornly maintained his earlier interpretation, to the justifiable astonishment of Lacroix. Actually, the possibility of transfer of

silicate-making materials was never widely admitted until the publication of Goldschmidt's proof (1921) that influx of silica and soda had accompanied the contact metamorphism of pelitic rocks in the Stavanger area. Before this convincing demonstration, and even afterwards, Cole⁶ (1915) and Thomas and Campbell Smith (1932), among others, took refuge in the unmanageable hypothesis that the big feldspars had somehow been bodily introduced from an assumed magmatic source. A fatal objection to this awkward idea is that the feldspars are to be found in obviously sedimentary contacts and enclaves, among which, as Read points out, there are examples where "delicate bedding displayed often in three dimensions, is not disturbed in the least." Innumerable exposures show that the feldspars cannot have been introduced mechanically. Harker ignored or minimized the evidence, and many other petrologists preferred to remain silent on the matter, presumably because they had nothing to say about what could not be understood. Nevertheless, a definite and far-reaching conclusion can be drawn in all cases where it can be established—as it generally can—that the feldspars did not grow as 'porphyritic' crystals of post-granite formation. To quote Read: "Where the xenoliths [enclaves] containing the feldspars are sedimentary, then what encloses the xenoliths and similar feldspars is also sedimentary—the porphyritic granites are produced from the sediments by an intensification of the feldspathization process", and, he pertinently adds, no one can demonstrate a magmatic origin for the porphyritic granite which contains the 'xenoliths'.

Meanwhile, as a result of several comparative studies of feldspathization and granitization, the French geologists became convinced that these processes increase in intensity downwards until the contact zones of the higher crustal levels merge into regions where the rocks have been quietly made over into granite without significant disturbance of the pre-existing strata. Both Michel Levy and Lacroix thought of the active agent as granite magma, but Lacroix makes it clear that the magma must have been chemically and physically very different from merely molten granite, since it generates granite only after incorporating the schists that were there before the granite. Termier (1904 and 1910) developed this conception to its logical conclusion by pointing out that the active magma envisaged by Lacroix could itself be accounted for in terms of pre-existing rocks and highly energized emanations. He speaks of the latter as *colonnes filtrantes*, which rise from the depths into, say, geosynclinal strata, adding energy and exchanging new elements for old as they ascend and spread out. Where the intensity is greatest the rocks are granitized and locally transformed into magma, while the displaced elements are driven forward with the other migrating materials in an advancing and slowly declining wave of metamorphism. Part of the magma generated in depth may invade the superstructure, forming granite intrusions with contacts of various kinds, including those of Rosenbusch's Barr-Andlau type. For Termier, regional metamorphism and intrusions (at all levels) "are but two effects of the same cause." Although Termier's impressive synthesis was too imaginative to command serious attention, it nevertheless foreshadowed much of the progress that has since been made in this complex field of research. In particular, we find in it a revival of Fournet's early hint of what has recently come to be known as the advance of the 'migmatite front'.

The term *migmatite* was proposed by Sederholm for rocks which suggest by their appearance that they originated "by the mixture of older rocks and a later erupted granite magma". Along the shores of southern Finland and its fringing archipelagoes the wave swept rock surfaces display spectacular examples of all the phenomena associated with granitization. By means of a series of lavishly illustrated memoirs (1907-34), as well as by conducting several international excursions, Sederholm made these challenging exposures so generally familiar that the baleful influence of the Rosenbusch school was at last effectively countered. Sederholm did not maintain his first conviction that what had injected and permeated the older rocks was a primary granite magma, but he seems never to have abandoned altogether the idea—although he wavered at times—that such magma was the ultimate source of the invading materials. He envisaged an ultra-metamorphic process referred to as *anatexis*, involving injection, solution, refusion, assimilation and differentiation, whereby new magma was formed. The newly born magma, having the original granite magma and the country rocks as its parents, became available in its turn for further migmatization. Later, he ascribed less importance to granite magma, whether primary or secondary, and more to what he called *ichor*, a derivative magmatic solution highly charged with water and other volatiles, and thereby endowed with great penetrative power. The primary granite magma thus became only a grandparent of the second generation of *ichor*. The weakness of this conception lies in the implication that relatively small quantities of *ichor*, though derived by magmatic differentiation, had nevertheless sufficient energy and chemical activity to promote *anatexis* on a regional scale and so to make more magma and more *ichor* out of large quantities of country rock. Evidently if the immigrating materials are to be capable of effecting granitization or *anatexis* on the scale observed, they must differ fundamentally in properties and origin from the late stage exudations of a granite magma as ordinarily conceived. For this reason the neutral term *emanations*, which is free from genetic implications, is now coming increasingly into favour.

Wegmann, now Argand's successor at Neuchâtel, has greatly clarified our ideas by the results of his long and detailed field studies in Finland (1931, in collaboration with Kranck) and Greenland (1935 and 1938). Wegmann is especially interested in the mechanism of *stoffwanderung*, the migration of atoms involved in migmatization and granitization, and has made familiar the concept of an advancing migmatite front. He is also a pioneer in the attempt to unravel the complex relationships between orogenic movements and atomic migrations. He draws a graphic distinction between

(a) migration of elements through a framework of earlier rocks which remains stationary and so retains its former structures, despite extensive exchange of materials and recrystallization, and

(b) migration through a framework which is itself deformed by movements during or after the migmatization, in this case relative movement between the more mobile migmatized parts and the more rigid parts of the framework leads inevitably to intrusive contacts, and when, as must often have happened, the final crystallization of such mobile masses outlasts the movements, the ancestral structures are obliterated, except perhaps for a few schlieren and enclaves, and the eventual result is a more or less massive granite

The leading exponent of the subject in Sweden is Backlund, whose views have developed along essentially similar lines. He has particularly discussed the transformations of rocks such as limestone, quartzite and metabasite and has shown how selective and progressive metasomatism dispels the chemical difficulties that seemed insuperable to Callaway and Bonney and, more recently, to Harker and Niggli, the granitizing materials that are retained and fixed vary with the composition of the rocks that are being granitized. He has also stressed the important fact that granitization has been a normal accompaniment of orogenesis throughout geological time. Read gives an admirable account of these recent Fennoscandian developments, including a summary of the spirited debate between Backlund and von Eckermann (1937-38) on the genesis of the rapakivi granites.

The geochemical relationships involved in granitization can be briefly summarized in the formula: granite = pre-existing rock *plus* added material (*A*) introduced by and abstracted from the incoming emanations ($A + x$), *minus* displaced material (*B*) driven forward with the outgoing emanations ($B + x$). When successive stages of the transformation of pre-existing rock into granite can be seen in the field, it is possible (provided that there has been no significant volume change) to determine *A* and *B*. The most notable work along these lines has been that of Doris L. Reynolds. In the course of her investigation of the Newry complex, she has proved by chemical analyses of carefully correlated specimens that the minimum introductions (*A*) required for the granitization of the country rocks were sodium, calcium and silicon, while, after several intermediate exchanges that are traced in detail, the displaced materials (*B*) eventually carried forward consisted of aluminium, iron, magnesium, potassium, hydrogen, titanium, phosphorus and manganese. The latter, together with some remaining sodium, calcium and silicon, became fixed in adjacent bands of hornfels which were thereby basified and transformed into rocks chemically equivalent to certain varieties of quartz-diorite. From these results and other relevant evidence, Dr Reynolds concludes

(a) that the introduced material ($A + x$) cannot have been an ordinary magma, since *x* has left no recognizable traces in the rocks,

(b) that the basic material migrating from a region of granitization, besides enriching the surrounding aureole in biotite and other minerals, was probably also responsible for the 'igneous-looking' basic and ultrabasic rocks that overlie the granitic rocks of many plutonic complexes, and

(c) that before a given mass of country rock was actually granitized, it passed through a preliminary stage of basification.

From the nature of the case, little can be said about the ultimate source of the granite-making emanations. The granophytic contact zones and rheomorphic veins locally associated with dolerite sills and dykes in non-orogenic regions indicate that at least some basaltic magmas have been capable of providing a limited supply. In depth, basaltic magma may be a potential source of considerable importance. In orogenic regions, however, attempts to relate the emanations to the supposed magmas of associated basic rocks are weakened by the possibility, in some cases confirmed, that such rocks have themselves originated as complementary by-products of the granitization process. The major processions of emanations may conceivably be liberated from abyssal magmas by differentiation,

or squeezed out of the intensely sheared roots of growing mountain ranges, or they may have a source of some quite unsuspected kind. But our ignorance of the source of orogenic emanations in no way militates against the evidence of their passage through the rocks. The origin of basaltic magma remains equally uncertain, despite many optimistic suggestions to the contrary. Read quotes with approval Kennedy's recognition (1938) of two contrasted expressions of magmatic activity, distinguished respectively as

(a) *volcanic* associations, derived from a parental basaltic magma which originates by the remelting of the earth's basaltic layer, and

(b) *plutonic* associations, derived from a parental granodioritic magma which originates where tectonic thickening of the crust brings the 'granite' layer within the range of melting, the ascent of such magma is preceded by an advancing wave of granitization and migmatization.

Since 1938, more precise estimates have been made of the heat generated in rocks by radioactivity, and of the crustal heat flow that escapes at the surface in Britain, South Africa and eastern North America. The results imply that in these non-volcanic regions the normal granitic and basaltic layers fall short of the temperatures required for magma formation by several hundreds of degrees.¹ In the light of the evidence now available, we can do no more than speculate as to how basaltic magma comes into existence. Where the granitic layer is greatly thickened in the roots of mountain ranges, the temperature at the base might eventually rise to the point required to start selective fusion, but many millions of years would be required, and even then latent heat would have to be supplied. The suggested process therefore fails to account for the observed fact that granitic rocks began to be formed (at levels well within the range of subsequent denudation) while the orogenic movements were actively in progress. Thus the whole problem of magma generation, apart from the possibilities associated with the emanation hypothesis, is still as baffling as ever.

There remains for consideration the all-important space problem. How have large masses (batholiths) of granitic rocks come to occupy their present positions, and what has happened to the rocks that were previously there? The bodily intrusion of gigantic volumes of magma appears to be mechanically impossible, and, as Read puts it "The only solution is to suggest that in fact no large bodies of granitic magma were in existence. The large granite masses result from replacement, they are granitization products. Many of the small granites may of course also be of the same origin, but some of them may result from the consolidation of magma and some from the consolidation of magma. Thus, though there may be granites and granites, most of them are of one kind and all of them may likely be of one connected origin." With this conclusion I am in full agreement.

VARIATIONS IN THE COMPOSITION OF THE SEA IN WEST AFRICAN WATERS

By DR. G. R. HOWAT
Government Chemist, Accra

THERE appears to be very little published scientific information about the chemical characteristics and plankton content of the sea along the West African coast except for observations made by various scientific expeditions passing through these waters, and there appears to be no published data in English of continuous observations made over a prolonged period. An opportunity to make such observations presented itself in 1943 and 1944, arising out of a scheme by the Gold Coast Government to develop the local fishing industry, and an attempt has been made to obtain some information of the variations occurring throughout the year in the chemical composition and plankton content of the inshore waters of the Gold Coast Colony. As no suitable craft was available for going far out to sea, the samples were taken at a point about one and a half miles from the shore in a depth of eight fathoms of water off Accra, the capital of the Colony. Samples were taken each week (with one or two exceptions) from the beginning of June 1943 to the end of September 1944. One sample was taken for chemical examination and one for a rough examination of the quantity and general character of the plankton content, both samples were taken 5-6 feet below the surface. The temperature of the samples was taken at the time of sampling, and salinity, dissolved oxygen, and phosphate were estimated in the laboratory. These results are shown graphically in Figs 1 and 2.

From Fig. 1 it will be seen that during this period the variation in temperature exceeded 10° C. The highest temperature recorded was 29.4° C on May 13, 1944, and the lowest was 19° C on August 3, 1943. The lowest temperature recorded in 1944 was 19.8° C on August 18. The relatively sudden and wide variations in temperature which occur between June and October are presumably a causative factor in the seasonal nature of the fishing in the waters of the Colony. As might be expected, the figures for the salinity (‰) given in Fig. 1 do not, with one exception, show any wide variations, but there is a slight increase observed in August and September both in 1943 and 1944. The rather low salinities observed at the beginning of July 1943 occurred at times of heavy rain.

The one wide variation referred to above occurred at the end of January and the beginning of February 1944. At that time the salinity fell from 33.93 on January 25 to 30.05 on February 9, and then rose sharply again to 34.95 on February 22. This very sudden fall is difficult to explain. It occurred at a time when there was no rain in the Accra district or along the coast. At this time, however, there was a strong east-to-west current and the only reasonable assumption is that large volumes of water from the River Volta formed a surface current which flowed westward as far as Accra.

The figures for the dissolved oxygen shown in Fig. 2 are the amounts of oxygen expressed as the percentage saturation. The figures show a surprising consistency during the greater part of the year. From the middle of October 1943 to the middle of July 1944 the saturation never exceeded 100 per cent or fell below 94 per

FIG 1

cent. The latter part of July, August and September brought wide variations both in 1943 and 1944.

The figures for the phosphate content given in Fig. 2 are the amounts of phosphate calculated as P_2O_5 per cubic metre. It will be observed that from the beginning of January to the end of March 1944 the amount of phosphate remained almost at zero, while July, August and September in both years saw moderately high values. The densities of the samples were determined at $80^\circ F.$ ($26.7^\circ C.$); the highest value was 1.0268 ($80^\circ/80^\circ$) on September 19 and 27, 1944, and the lowest was 1.0226 ($80^\circ/80^\circ$) on February 10, 1944.

As no trained marine biologist was available to undertake full examination of the plankton samples, their investigation was not so complete as could be desired, so only certain broad generalizations can be made. The vegetative plankton was found to consist of diatoms, chiefly *Chaetoceros* spp., *Coscinodiscus* spp., and *Rhizosolenia* spp., and dinoflagellates such as *Ceratium* spp. and *Dinophysis* sp. The animal plankton consisted almost entirely of crustaceans and *Sagitta* sp. The crustaceans were mostly various species of copepods, but numbers of the larval forms of larger crustaceans were found. Several species of echino-

derm larvæ were also taken in the tow-net, and on one or two occasions fish eggs were seen.

It was found that the character of the plankton samples changed considerably during the period under review. In June 1943 the samples were moderate in quantity and were composed chiefly of copepods and *Sagitta* sp. In July, August, and part of September 1943, the samples consisted almost entirely of diatoms, chains of *Chaetoceros* spp. being specially abundant. After the end of September, apart from a few *Coscinodiscus* spp., practically no diatoms were observed, the samples being composed of copepods and *Sagitta* sp. In January, February and March 1944 the samples were, generally, poor in quantity and were composed chiefly of copepods

and a few *Sagitta* sp. In April and May the quantity was generally larger and the samples were again composed of copepods and *Sagitta* sp. with a number of larval medusæ. At the beginning of June, diatoms began to appear in some quantity, although the catch was still composed chiefly of copepods. Later on in the month *Coscinodiscus* sp. and *Ceratium* spp. were also present, again with a large number of copepods. In July the quantity of the samples was considerably larger, and by the end of that month there were only a few copepods present and the bulk of the catch was *Coscinodiscus* sp. and chains of *Chaetoceros* spp. During this month, too, a considerable number of echino-

FIG 2

derm larvæ were observed. The character of the samples remained the same during the first part of August, but in addition some *Rhizosolenia* spp. (?) were observed. On August 16 a very unusual phenomenon was observed when taking the water sample. The sea was found to be a distinct chocolate-brown colour and very turbid. A sample was taken in a glass jar and the colour was seen to be due to vast numbers of a small greenish-brown organism just sufficiently large to be distinguished by the naked eye. Examination in the laboratory later on showed it to be a flagellated organism, which I was unable to identify. The plankton sample consisted almost entirely of masses of this organism. I do not know how far the coloration extended, but it was observed from aircraft for at least 70 miles along the coast. The phenomenon persisted for days, and when the next weekly sample was taken there were still masses of the organism in the plankton sample. During the first part of September *Coscinodiscus* sp and *Chaetoceros* spp composed the bulk of the catch, and later on *Noctiluca* sp (probably *N. scintillans*) predominated.

An examination of the data obtained from the samples appears to indicate that there is an influx of cold ocean water along the sea-board of the Colony during the months of July, August and September. This may be due to an upwelling of deep ocean water on to the continental shelf, or to cold ocean water from the South Atlantic Ocean finding its way into the current which flows for the greater part of the year from west to east along the sea-board of the Colony. It is probably not without significance that this influx of cold water, slightly more saline and richer in phosphate, coincides roughly with the main fishing season along the greater part of the coast of the Colony, when two species of *Sardinella*—*S. aurata* and *S. cameronensis*—are caught in large quantities.

It is hoped to continue and extend this work in the near future.

THE PUBLIC SCHOOLS OF BRITAIN

By the REV. CANON SPENCER LEESON

Headmaster, Winchester College

THE public schools question has been somewhat in abeyance in recent months. Among the reasons for this is that the larger share of public attention in this province has been given to the Education Act, and the numerous administrative measures that are required to bring it into effective operation, and also that up to now the negotiations between the Ministry, on one hand, and the associations of governing bodies for boys' schools and girls' schools, the headmasters and headmistresses on the other, have been confined to scheme A of the Fleming Report, that is, the recommendations applying to what will be known in the future as direct-grant grammar schools. These negotiations are pretty well completed, and the revised regulations for direct-grant grammar schools have now been published. Discussions on scheme B, that is, those recommendations that affect mainly the independent boarding schools and day schools, are just beginning, and we may therefore expect a revival of public interest in the future of those schools.

The Fleming Committee is to be warmly congratu-

lated on producing a unanimous report on so difficult and controversial a question, and its whole discussion of the matter and its recommendations are clearly based on a wide and deep knowledge of conditions prevailing in the schools, and the concrete problems that have to be solved. Various proposals were put before them for the future regulation of the public schools. One extreme view was that they should be abolished altogether, their endowments taken over and their buildings dedicated to other educational purposes, hostels, residential courses in adult education and so forth. It is not likely that this view will be supported in any responsible quarter. Another suggestion was that the schools should be kept in operation, but should be handed over to the State to be run as part of the State educational service, boys and girls being allocated to them by public authority, and the schools being brought under full public control. The third proposal is that put forward by the Fleming Committee, namely, that the schools should remain independent, although open to inspection by the Ministry of Education and accepting to membership of their governing bodies public representatives up to not more than one third of the total number, and that they should reserve each year 25 per cent of their admissions for boys and girls who have previously been educated at primary schools, the expense, as calculated on a fee to be agreed upon for each school between the schools and the Ministry, to be met from public funds in so far as the parents themselves are unable to pay the full cost. It is around these recommendations that, no doubt, the coming negotiations will centre; and we may hope that in a few months some measure of agreement will be reached. It is made clear in the report that the co-operation of the schools is to be voluntary from their side and that no compulsion should be applied to them.

I submit that in the settlement of this great national question we should endeavour to free ourselves from political preconceptions and prejudice on both sides. History shows that politics is no friend to education, and that where political considerations and especially party considerations are allowed to come in from either end, the work of the schools suffers. I suggest that we should put all this on one side and base ourselves on two propositions. The first is contained in section 76 of the Education Act, 1944: "In the exercise and performance of all powers and duties conferred and imposed on them by this Act, the Minister and Local Education Authorities shall have regard to the general principle that, so far as is compatible with the provision of efficient instruction and training and the avoidance of unreasonable public expense, pupils are to be educated in accordance with the wishes of their parents". The second proposition is contained in the first recommendation on p. 100 of the Fleming Report: "that opportunities of education in the schools included in our terms of reference (i.e., roughly speaking, the public schools), and in any such other schools as may be approved for the purpose by the Ministry of Education, be made available to boys and girls capable of profiting thereby, irrespective of the income of their parents". No considerations other than these have really any bearing on the matter. If it is argued that ex-primary pupils should be taken into the schools at public expense in order to preserve the latter from extinction, that argument has no validity; if the schools cannot stand on their own feet, they had much better disappear. On the

other side, if it is argued that this infiltration, as it is called, of boys of one class into schools up to now reserved for boys of other classes, will have the effect of de-classing them, as it were, and detaching them from their former political and social allegiance, that also has no validity. Both are good examples of the wrong kind of approach. The only sensible and natural approach is surely this. Are there any parents who want their children to have boarding school education? If so, is it fair or right that they should be debarred from obtaining that education for their children because they cannot afford to pay the fees? Clearly the answer to this second question must be No. If the public schools have worked out an educational method and standard that parents believe to be valuable, ought access to those schools to be confined, as it is now, to exceptionally clever boys who win scholarships, and boys whose parents can afford to pay high fees? Clearly, again, the answer must be No. How, then, can we put matters right? I suggest by the adoption of a double-pronged policy, first that the State should provide boarding schools of its own, and power to do this is conferred upon the State by the Act, and secondly, that the existing boarding schools should take post side-by-side with these schools that soon, we hope, will be created, making their contribution under proper conditions, but preserving their independence. This policy will give rein to the incontestable right of parents to decide within reasonable limits how their children shall be educated, and it will at the same time enable the public schools to make their offer without forfeiting their independence.

It may be asserted, in reply. Why should the schools be allowed to retain their independence? On that the schools are unanimous and emphatic. It is not in the public interest that all schools of every kind should be controlled by the State, and this principle is conceded by Parliament in the Act. It is not the business of the State to control all education because it is the State, but rather to encourage good work wherever it is being done, and to supplement the existing provision where the latter cannot cover the ground. Spiritual and intellectual liberties of the highest significance for the welfare of Britain are involved in this, and it is probable that if, as a condition of participating in this or any other scheme, the schools are asked to surrender their independence, they will have nothing further to do with the matter. They would, I believe, be unanimous in welcoming, as they are now under the Act required to accept, inspection by the Ministry, and personally I can see no objection to the inclusion of public representatives in the proportion suggested on the governing bodies. There, however, external supervision should stop.

There are a large number of details that will have to be worked out and which cannot, owing to limitations of space, be set out in this article—for example, the age of entry, methods of selection, the preparatory stage, assessment of parental and other contributions, agreement upon the standard fee, etc. Two general considerations can be urged at this stage. First, the schools are at present crowded to overflowing, the public demand for them is great, and it may therefore take some time for them to work up to the full 25 per cent, if that recommendation should be accepted. Secondly, the report makes a fine offer to boys who have been previously educated at primary schools, and we may hope that nobody will seek to encroach upon or limit that offer to those

boys. But it remains true that very little is offered to parents in straitened circumstances, poor professional men, who have not sent their children to primary schools. In the interests of justice and equality it is clear that later on, if not now, measures will have to be taken to open the door to the children of these parents also.

During the last six years many pages have been written on the public schools, some of the authors being inspired by an irrational adulation of everything they do, and others by an equally irrational detestation of them and all their works. It may be hoped that during the months that are approaching all that sort of nonsense may be forgotten. The plain fact is that the schools have something to offer, and the plain question is, How can that be made use of in the interests of the nation as a whole? The latest volume on the public schools is called "The Public Schools and the Nation", by Dr A. B. Badger*. This is based on some careful research going back to the sixteenth century. The general tone of the book is critical, and no one who values the contribution made in the past, and to be made in the future, by the public schools will ever object to having their faults candidly pointed out. The general effect of the book is somewhat confusing, as it consists so largely of quotations from the opinions of other people, many of them expressed a number of years ago, and applying, therefore, to conditions which have long since ceased to exist in the schools. Readers will welcome Dr Badger's compilation and be grateful to him for his research, but the best of all guidance to future policy is to be found in personal, up-to-date, first-hand acquaintance with what the schools are and what they try to do.

* The Public Schools and the Nation. By Dr Alfred B. Badger. Pp. 160. (London: Robert Hale, Ltd., 1944.) 8s. 6d. net.

OBITUARIES

Sir Duncan Wilson, C.V.O., C.B.E.

SIR DUNCAN WILSON who, until his resignation in 1940 was chief inspector of factories, died suddenly on March 2 in his seventieth year. On leaving Eton he entered Magdalen College, Oxford, where he took his degree with first-class honours in natural science, and although his life-work has mainly been in administration, yet his scientific training proved a very valuable asset.

His official career falls roughly into three main periods. For fourteen years from 1904 he was a factory inspector, then came twelve years in which, as secretary, he organized the Industrial Fatigue (later Health) Research Board, after which he returned to his old department, first as deputy and then as chief inspector of factories.

Perhaps the mid-period gave Sir Duncan the greatest opportunity to use his scientific knowledge and to express his individuality. The Industrial Fatigue Research Board was a very small organization, formed at the dissolution of the Health of Munition Workers' Committee at the end of the War of 1914-18, to apply the principles of physiology and psychology to research into industrial problems. In his first annual report published in 1920 he wrote, "The scientific study of the laws governing the healthy employment of the human mind and body in industry was strangely late in its development in this country,

although it was in Great Britain that the industrial revolution had its first beginnings and industrial development was most rapid." In his next report he introduced the same theme, "Industries for the most part are not yet fully alive to the importance of the human factor in production and to the still greater part this is destined to play in the future." It is partly due to the early work of Sir Duncan that these words are less true now.

In his early organization each investigator was responsible for a particular industry, and the investigators concerned themselves principally with hours of labour and the general environmental conditions likely to cause undue fatigue. As time went on investigators developed individual interests and worked along more specialized lines. As an organizer, Sir Duncan interfered as little as possible with his staff, although he was always willing to help where help was needed, either in making arrangements with a particular firm, or advising on the form of a report, and no small part of the work of the Industrial Health Research Board has been made possible by his unobtrusive but valuable help. By 1930 there had been published fifty-six reports dealing with hours of labour, lighting, heating and ventilation, vocational guidance, boredom, accidents, time and motion study.

There was an entire absence of 'red tape' in his dealings with his staff, and all, however junior, could have access to him. He had a remarkable poise of personality which made him at home with people of all ages and social class. He could without conscious effort talk equally easily to a factory worker or a duchess, to an industrial magnate or a humble apprentice, and to go round a factory with him was invariably a valuable experience. He was unusually scrupulous in giving credit to researchers and in acknowledging their work. He had many interests outside his work and was an excellent amateur musician.

Sir Duncan's official retirement was in name only, for he carried on numerous activities after the outbreak of war, serving as chairman of the National Industrial Electric Lighting Service and of the Home Office Committee on Factory Lighting, a subject that had always been of great interest to him. He will, however, always be affectionately remembered by his colleagues for his humanity.

Prof. Paul Bertrand

SON of the distinguished palaeobotanist [Charles Eugène Bertrand (1851-1917), Paul Bertrand, the report of whose death has recently reached Great Britain, followed up his father's work on fossil plants, and became a leader in palaeobotanical research. He was professor of palaeobotany in Lille until 1938, when he was appointed to the chair of comparative anatomy for the study of fossil plants at Paris. He died in Paris after a short illness aggravated by privation and anxiety on February 24, 1944.

Most of Bertrand's published work falls within the period 1910-39. His most important contributions to the literature of his subject fall into two groups. His work on the Carboniferous floras of the French coal-measures has proved indispensable to students of Carboniferous stratigraphy in Europe and America. His recognition and demonstration of stages or zones in the succession of vegetation in the Carboniferous which could be recognized and defined by their floristic composition will remain, just as the corre-

sponding work by Kidston in Britain, a classic example of the application of palaeobotanical research to geology. Their work has led up to more recent work by Dr Dix in South Wales and by many workers in North America. As an accompaniment to this work he produced monographs of outstanding quality on the Pteridosperm genera *Alethopteris*, *Mariopteris* and *Neuropteris*.

The essence of all this research is contained in Bertrand's contributions to the *Comptes rendus* of the Congresses on Carboniferous Stratigraphy held in Heerlen in Holland in 1927 and 1935. On the botanical side, his work on Algæ (Botryococcaceæ) found as constituents of certain coals, and on the anatomy of Devonian and Carboniferous ferns, is of outstanding quality and importance. Here he ranks with Williamson, Scott, Kidston and Lang as an outstanding contributor to our knowledge of the anatomy of Devonian and Carboniferous plants.

Bertrand kept in touch with a wide circle of friends interested in palaeobotanical work, and, with Mme Bertrand, who survives him, regularly attended international meetings. Those who were privileged to know him will remember his quiet unassuming character, and his unfailing sympathy and interest in his friends' difficulties and problems. To know the Bertrands was to know what is best and most charming in the French character. His death causes an irreparable loss to many—especially to his younger colleagues, to whom he was unfailingly helpful.

JOHN WALTON

Dr Max Bergmann

DR MAX BERGMANN, the distinguished chemist, died in New York on November 7, 1944, at the age of fifty-eight. Dr Bergmann, who was born in Fuerth, Bavaria, studied chemistry in Munich and received his Ph.D. degree in the University of Berlin in 1911. He then entered the laboratory of Emil Fischer, where he worked until the latter's death in 1919. In 1921 Bergmann became director of the Kaiser Wilhelm Institute for Leather Research in Dresden, a position which he held until 1934. Shortly after Hitler came to power, Bergmann, being a Jew, resigned his post and accepted the position of an associate member of the Rockefeller Institute for Medical Research in New York. He was appointed a member of the Institute in 1937 and occupied this position at the time of his death.

Bergmann's work up to the time when he left Germany followed fairly closely both in subject-matter and in his way of approach that of his great master, Emil Fischer. It was concerned, almost exclusively, with the organic chemistry of amino-acids and carbohydrates. Fischer had discovered a new class of sugar derivatives, the glycals, but Bergmann proved that the structure assigned to them was not correct. He showed that these compounds were not aldehydes as Fischer had assumed, and also demonstrated the presence and position of a double bond and established the size of the ring. Another field of sugar chemistry in which Bergmann made notable contributions was that of chitin and glucosamine. His isolation of the disaccharide, chitobiose, was contemporary with that of Zechmeister.

The main interest of Bergmann was, however, in amino-acids. He extended greatly our knowledge of the azlactones, the highly reactive unsaturated anhydrides formed from amino-acids, his last paper, which appeared after his death, was devoted to this

subject. He was interested in most aspects of the organic chemistry of amino-acids, and it is difficult to single out particular contributions. His work was distinguished by a real elegance in conception and great skill in execution. Thus, his model experiments on the formation of creatine from arginine anticipated by many years more recent work on the occurrence of this reaction in the living animal. Bergmann's papers covered the problems of acyl migration, racemization, reactions of β -hydroxy- α -amino-acids, unsaturated peptides, and many others. His crowning achievement during that period was, however, his novel and important general method of peptide synthesis. The classical methods of Fischer permitted only the preparation of peptides made from simple amino-acids. Bergmann's new method made use of N-carbobenzoxy derivatives of amino-acids; the acyl substituent protected the amino-group during the condensation and could afterwards be easily removed by catalytic reduction. This new method made possible the synthesis of almost any desired peptide.

Bergmann's work during his second, American, period was turning away from pure classical, organic chemistry, and more concerned with the structure and biochemistry of proteins. He showed for the

first time that the pure crystalline, peptic and tryptic enzymes which had been prepared by Northrop and his school would act not only on proteins, as had been thought hitherto, but also on certain peptides. The work dealing with the substrate specificity of these enzymes was of much importance for our knowledge of enzymes and helped greatly towards a better understanding of the structure of proteins. Bergmann's work also extended to the proteinases of plants and those of animal tissues. Another field in which Bergmann made very important contributions was that of the analysis and isolation of amino-acids present in proteins; he discovered many specific precipitating agents for amino-acids and devised new and interesting methods of analysis. Together with Niemann he formulated the so-called 'frequency-law', which assumed that the different amino-acids in a protein molecule are present in certain restricted proportions. Although the exact quantitative relationships assumed may have to be modified, the emphasis on stoichiometric regularities has greatly stimulated analytical work and focused attention on the regularity of the internal architecture of protein molecules.

The loss of Dr. Bergmann will be felt by organic chemists and biochemists all over the world; he leaves a widow and two children. A. NEUBERGER

NEWS and VIEWS

Glass Technology at Sheffield:

Prof W. E. S. Turner, O.B.E., F.R.S.

THE announcement that Prof W. E. S. Turner is to retire from the chair of glass technology in the University of Sheffield, which he has held since 1920, comes as rather a shock. Prof Turner's name has become so closely associated with the application of scientific principles to glass manufacture that it is hard to visualize the industry without this association. In 1914, Prof Turner was responsible for the setting up of a Scientific Advisory Committee of the University of Sheffield to deal with technical problems arising in the local industries and, following on this work, was led to prepare a report on conditions in the glass industry. This report also made recommendations to the University Council, with the result that a Department of Glass Technology was set up in June 1915. This work was organized by Dr Turner, as he then was, and in 1920 the Council converted this Department to a chair of the University. From that date to the present, Prof Turner has made and established a name in connexion with the glass industry which will stand for all time.

Prof Turner founded the Society of Glass Technology in 1916, and has been editor of the Society's journal throughout its existence. He has been president of the Society on two occasions, 1922-24 and 1937-38, and has acted as secretary for three long periods. Prof Turner has also been instrumental in initiating international meetings between glass technologists in America, France, Belgium, Germany and Denmark, founding the International Congress on Glass, the first meeting of which was held in Milan in 1933. He was also responsible for instituting the Glass Convention, which brought together industrialists, administrators, commercial representatives and glass technologists. The teaching work of the Department under his guidance has been of such importance that many of his former students now occupy

important positions throughout the industry. His researches cover the whole range of glass technology and scientific research into glass and related problems. There can be few instances where one man has become so closely identified with an industry and where, in the lifetime of one man, and to a great extent due to his efforts, that industry has developed from one depending almost entirely on craftsmanship to the position where scientific control and mechanized processes have been so fully established.

Dr. Harry Moore

DR HARRY MOORE, who has been appointed by the Council of the University of Sheffield to succeed Prof Turner on his retirement, will bring with him to the task the benefit of a broad academic training and research experience, coupled with exceptionally wide and specialized technological knowledge. After a distinguished student career at the Royal College of Science during 1904-7, followed by a year as a demonstrator in the Physics Department of the College, he was, in 1908, appointed lecturer in physics at King's College, London, a post which he held until 1915. While there he published in the *Philosophical Magazine*, the *Proceedings of the Royal Society* and the *Proceedings of the Physical Society* papers on the influence of X-rays on various substances. Another group of papers on X-rays appeared between 1924 and 1928 in the *British Journal of Radiology*. During 1915-19 he was busy in connexion with Ministry of Munitions training schemes, finally being transferred to the Ministry of Labour Training Department as chief technical officer for south-west England. In 1919 he was appointed assistant director of research of the British Scientific Instrument Research Association under Sir Herbert Jackson, and when Sir Herbert retired in 1933, Dr Moore succeeded him. In 1937, Messrs Pilkington Brothers decided to build and equip extensive research laboratories and invited

Dr Moore to become the first director, a post which he still holds. He has served for some twenty-five years on committees of the British Standards Institution dealing with subjects related to instruments and to glasses for a variety of purposes, and since 1933 on the inter-departmental committee on optical glass set up by the three Service Departments. In April 1944 Dr Moore was elected to the presidency of the Society of Glass Technology, and has been nominated for a second year of office. Dr Moore, with his wise and genial personality and his wide experience of glass and its manifold applications, is an excellent choice for the variety of important activities centred in the work of the Department of Glass Technology of the University of Sheffield.

Fisheries Adviser at the Colonial Office

Mr. C. F. Hickling

THE Secretary of State for the Colonies has appointed Mr C. F. Hickling to be his fisheries adviser. This is the first time that the position has been filled on a permanent and full-time basis. Mr Hickling's predecessor, Dr E. S. Russell, having acted in a part-time capacity during a period of approximately two years. The possibilities for development and research in Colonial fisheries are very considerable, and the post of fisheries adviser is one of great opportunity. Mr Hickling, who will take up his duties immediately, will be assisted and supported in his task by the Colonial Fisheries Advisory Committee which was appointed in 1943.

After taking his degree at Cambridge, Mr Hickling engaged in postgraduate research at the Marine Biological Laboratory, Plymouth, and the Department of Oceanography, University of Liverpool, and in 1927 was appointed to the fishery research staff of the Ministry of Agriculture and Fisheries, in which he rose to the rank of senior naturalist. His work as a fishery investigator was of a high order; he published in several parts an excellent monograph on the hake and the hake fisheries, on which he became an acknowledged authority, together with many other papers on cognate subjects. His Buckland Lectures on the hake were published in 1934. During the War he has been acting as port fishery captain at Milford Haven with conspicuous success, and he has also found time to make a statistical study of the effects of the War upon the hake stocks, as yet unpublished.

Colonial Medical Research Committee

THE Secretary of State for the Colonies and the Medical Research Council have jointly created a Colonial Medical Research Committee to advise them on medical research for the benefit of Colonial territories. It is constituted as follows: Sir Edward Mellanby, secretary of the Medical Research Council (chairman), Colonel J. S. K. Boyd; Prof. P. A. Buxton, professor of entomology, London School of Hygiene and Tropical Medicine; Dr A. N. Drury, director of the Lister Institute of Preventive Medicine; Brigadier N. Hamilton Fairley; Dr W. H. Kauntze, chief medical adviser to the Secretary of State for the Colonies; Prof. B. G. Maegraith, professor of tropical medicine at the Liverpool School of Tropical Medicine; Dr B. S. Platt, director of the Human Nutrition Research Unit, Medical Research Council; and Major-General Sir John Taylor. The secretary of the Committee is Dr F. Hawking, of the National Institute for Medical Research, London, N.W.3.

Restoration of Pulkovo and Kiev Observatories

A FIVE-YEAR plan for rebuilding the famous observatory at Pulkovo on the outskirts of Leningrad is announced by the Academy of Sciences of the U.S.S.R. The main building is to be restored as it was originally, and such of the valuable equipment and instruments as were removed to safety before the Germans began the bombardment of the besieged city will be installed again. The Observatory was completely destroyed, and the cost of reinstatement is estimated at 137 million roubles. The world-renowned library could not be removed in time, and many irreplaceable books and manuscripts are lost to posterity. Adequate provision to restock the library includes the earmarking of 200,000 dollars for purchases abroad. Plans for work in the future suggest that the character of the institution is not to be changed: both fundamental astronomical work and astrophysical researches will be undertaken.

At Kiev, where less damage was done, work is so far advanced that this year's centenary of the foundation of the Observatory should see the whole of the staff back at work in a reconstructed establishment. With more warning of what was coming than their Pulkovo colleagues, the Ukrainian astronomers were able to transport most of the instrumental equipment to Sverdlovsk, 3,000 km. to the east, where they were given refuge during the occupation. On their return they found the observatory buildings empty, plundered and partly ruined by the fleeing Nazi army. Rebuilding has proceeded at such a speed, however, that new pavilions already house the 257-mm. refractor and the 120-mm. meridian circle, and regular observations and instruction have started again. Extensions on which work has already begun include a building for a proposed big modern refractor, an astrophysical laboratory and a deep basement for seismic work.

Technical Education in Scotland

SCOTLAND, a country that has long been education-conscious, is fully alive to the importance of technical education in modern social life, and the Interim Report on Technical Education recently issued by the Special Committee of the Advisory Council on Education in Scotland (H.M. Stationery Office, Edinburgh, 3d) advocates national planning on an extensive scale in order to bring training facilities within the reach of all. The core of the planning consists in the proposed establishment of a National Advisory Council for Technical Education, and four regional advisory councils (with a fifth for the Highlands, if necessary), all fully representative of industrial, commercial and educational interests, in order to survey both national and local requirements and to co-ordinate development schemes. The needs of part-time as well as full-time students have been considered in connexion with the organization of central institutions and local technical colleges, the former capable of dealing with work of the most advanced type and in some cases performing the functions of peak institutions for specialized subjects; technical instruction is also envisaged in the new colleges for compulsory further education of young persons and in voluntary day and evening classes where technical colleges cannot be established. It is realized that the new proposals will involve heavy financial commitments, and the National Council would therefore be required to make recommendations to the Secretary of State as to expenditure that is desirable. The proposals in the report are on a bold scale and well

calculated to produce a system of technical education to match the great literary and academic achievements of Scotland, which have perhaps in the past tended to obscure the activities of the technician, the artisan and the craftsman

A National Health Service

IN "Health Abounding", issued by the Social Credit Party, 2 Fitzroy Street, London, W 1, Dr A T Westlake describes the aims of the health service which is planned by the Social Credit Party. Dr Westlake begins with some telling remarks about our existing health services and about the Government's proposals for a national health service. Our existing health services are complex and confused, and we fail to apply the knowledge that we possess. Health is largely dependent on our ability to pay for it, in spite of numerous charities and the altruism of the medical profession. Our existing health organization has, Dr Westlake thinks, produced a magnificent service, but it contains fatal flaws, the most glaring of which is the making of a living out of ill-health. The Government's proposals for a national health scheme and the Beveridge proposals have brought matters to a head. All seem to be agreed that the future medical service will be a complete and comprehensive one covering everybody, but the problem is how best to create it. The Medical Practitioners' Union, the Socialist Medical Association and several other bodies advocate a State Medical Service, the British Medical Association seeks a compromise between the old system and the new proposals. A State medical service under present conditions can only mean, Dr Westlake argues, rigid control of both medical man and patient, with strict certification. The Government's White Paper is not a health scheme, but a medical and sickness service, it is not a free service, for it is to be paid for by taxation, rates and social insurance. The only basis upon which can we have a free State medical service which leaves the medical man a free agent is, Dr Westlake thinks, the Social Credit System.

The two main objects of this health service would be the health of the community organized into the cure, annihilation and prevention of disease and the promotion and maintenance of health, and the well-being and skill of all those who work in the health service. Curative work will for some time engage most of its attention, because of the gigantic proportions of the disease problem. No one is likely to object to Dr Westlake's excellent suggestions under this heading. He would treat the mind as well as the body, deal drastically with the patent medicine racket and create real health centres which would cater primarily for the healthy and only secondarily for the diseased, for whom curative centres would be provided. Dr Westlake here draws much on the experience of the Peckham Health Centre, which has provided valuable information. Prevention of disease depends on the abolition of poverty and on proper feeding, proper housing and elimination of industrial over-fatigue. These are the problems of social medicine, which is vitally important. Problems of immunization and health education are also discussed. In his discussion of health, Dr Westlake again refers to the work of the Peckham Health Centre. Not everyone will agree with the development of this section of the pamphlet, or with Dr Westlake's conception of a medical guild for the promotion of health and well-being. The General Medical Council exists for the protection, not of the

medical profession, but of the public. Dr Westlake would add to its functions the welfare and interests of the medical men also. Further sections of his pamphlet deal with administration, finance, hospitals and other details.

The Case for 'Planning'

THERE pamphlets issued by the Cheam Architectural Press (price 6d each) in "The Planning Bogies" series are too good to be popular. Those who dislike Prof H J Laski are unlikely to be pleased with the way in which in "Will Planning Restrict Freedom?" he disposes of the bogie of bureaucracy, and the more ardent planners may be restive under his trenchant delineation of the conditions which planning machinery must serve in a democracy—his insistence on the participation of the ordinary citizen is, moreover, reflected in the other pamphlets. Mr E S Watkins in "How Will Planning Affect Land Ownership?" deals with nationalization, but the pamphlet also gives an admirably lucid explanation of the existing land ownership system in Britain and of proposals for reform as contained in the Uthwatt Report and elsewhere. The broad objectives of land control—to ensure both the best economic and the best social use of our land and resources—are well stated, and also the basic requirements of control, they lead to concrete suggestions as to the composition and areas of planning authorities and amendments to the Town and Country Planning Act, which would transfer the responsibility for planning from the existing local government authorities to *ad hoc* area planning committees.

Mr E F Schumacher, in examining the question "What Will Planning Mean in Terms of Money?", discusses first the case for physical planning, he believes that, when the social costs of unplanned development are taken into account, the question becomes rather whether we can afford to do without planning. Emphasizing the growing divergence between private and social costs, he examines the case for housing in further detail, and argues that physical planning is the pre-condition for the successful pursuit of a housing programme such as the Government is preparing to inaugurate. Without it a steady effective demand cannot be maintained, the programme will be wasteful and head for an early collapse.

New Electron Microscope for Canada

THE National Research Council of Canada announces the installation of the latest type of electron microscope in its Ottawa laboratories. This instrument and one developed in the Physics Department, of the University of Toronto are the first electron microscopes to be used in Canada. A third microscope will be installed shortly at McGill University in Montreal. Plans to purchase this modern research instrument were made a year ago when the Council sent two physicists to the United States to study the available types. After the new RCA Universal model was selected, priority application was made to the United States War Production Board, which scheduled delivery for January 1945. The Division of Physics and Electrical Engineering has provided laboratory space for the microscope and assigned a physicist in the Radiology Section to take charge of it. It is hoped to make this new electron microscope as widely available in Canada as possible to all Government laboratories and to those industries having suitable problems.

Recent Earthquakes Recorded in the British Isles

THE earthquake widely noted in Britain on December 30, 1944, was recorded at Kew. From a preliminary reading of the record, it appears to have registered first at 00h 36m 14s GMT from an epicentral distance of 300 km. This would make the initial time of the shock 00h 35m 35s GMT. Four strong shocks were recorded at Kew between January 9 and February 13, 1945. The strongest was on February 10, when an earthquake beginning in the region of Japan attained a ground amplitude of 145μ at Kew. Mr E W Pollard recorded two strong shocks on January 12 and 18, and earthquakes or tremors on February 10, 13, 17, 18 and 26 at his observatory at Binstead, Isle of Wight. The United States Coast and Geodetic Survey determined the epicentre of the earthquake of January 1, 1945, to have been near Baffin Bay.

War and Infectious Diseases

AT a Chadwick Lecture on this subject delivered on February 20 at the Royal Society of Tropical Medicine and Hygiene, Dr J D Rolleston discussed the various acute infectious diseases in relation to war in the following alphabetical order: cerebrospinal fever, diphtheria, dysentery, enteric fever, infectious hepatitis, malaria, measles, mumps, scarlet fever, small-pox, streptococcal infections, typhus fever and war wounds. Chronic infections, particularly tuberculosis and syphilis, were not considered. Comparative novelties mentioned in the lecture included diphtheria of the skin, infective hepatitis, the striking decline in the incidence and mortality of enteric fever, and the introduction of new specific remedies, of which the most valuable were penicillin for war wounds, sulphaguanidine for dysentery and atabrin for malaria.

Poliomyelitis Epidemic in America

ACCORDING to Mr B O Connon, president of the National Foundation for Infantile Paralysis (*J Roy Inst Pub Health and Hyg*, Feb), the 1944 epidemic in the United States has been the second worst in the recorded history of the disease. The seven States most severely menaced are New York, North Carolina, Pennsylvania, New Jersey, Virginia, Ohio and Kentucky. The peak of the epidemic was reached in the week ending September 2, when 1,683 cases were reported.

Colonial Office Appointments

THE following appointments have recently been made in the Colonial Services: D P Pielou, to be entomologist, Northern Rhodesia; E G A Benson, agricultural superintendent, British Guiana, to be agricultural officer, Trinidad; J D Brown, senior agricultural officer, Nigeria, to be principal agricultural officer, Nigeria; M A G Hanschell, agricultural superintendent, British Guiana, to be agricultural officer, Sierra Leone; L P Henderson, agricultural officer, Nigeria, to be senior agricultural officer, Nigeria; A Pitcairn, assistant director of agriculture, Cyprus, to be senior agricultural officer (supernumerary), Tanganyika; F E V Smith, principal assistant secretary (Development Branch), Nigeria, to be development secretary, Nigeria; C B Taylor, agricultural officer, Nigeria, to be senior agricultural officer, Nigeria; D H Urquhart, assistant director of agriculture, Nigeria, to be director

of agriculture, Gold Coast; R G M Willan, assistant conservator of forests, Cyprus, to be assistant conservator of forests, Nyasaland; E D Fort, surveyor, Gold Coast, to be senior surveyor, Gold Coast.

Prizes for Scientific Instrument Manufacture

MR W BOWEN, governing director of the Bowen Instrument Co, Ltd, Cables and Plastics, Ltd, and Bowen Research, has presented to the Scientific Instrument Manufacturers' Association a substantial capital sum, the income of which he wishes to be devoted towards the encouragement and development of invention, design, research, processes and manufacturing technique in the scientific instrument manufacturing industry. The Council of the Association has accordingly drawn up a deed of trust under which the income from the fund is to be devoted each year to prizes to be awarded to the employees of members submitting papers fulfilling the objects of the trust. For the current year the Council has decided to award five prizes to the value of £25 each for (a) a new invention, (b) an improvement of design, (c) an improvement in manufacturing technique, (d) a new development or new process arising from research, and a list of topics defining the subjects or instruments admissible has been drawn up. Candidates should furnish a short description of one of the above subjects not exceeding 3,000 words with relevant sketches or diagrams, and they must be employees of members of the Association. All papers must be submitted to the secretaries of the Association, Messrs Bunder, Hamlyn and Co, River Plate House, 12-13 South Place, London, EC 2, not later than December 31, 1945.

Announcements

DR N FEATHER, lecturer in physics in the University of Cambridge, has been appointed professor of natural philosophy in the University of Edinburgh, in succession to the late Prof C G. Barkla.

DR L C BURRILL has been appointed professor of naval architecture at King's College, Newcastle-upon-Tyne, as from October 1, 1945. Dr Burrill is thirty-nine years of age. He has had a wide practical experience of naval architecture with Messrs Swan Hunter and Wigham Richardson, Ltd (1929-34), and the Manganese Bronze and Brass Co, Ltd, where he has held the position of naval architect since 1936. In addition to extensive research resulting in the recent award of the degrees of M Sc and Ph D in naval architecture, he also lectured at the Rutherford Technical College, Newcastle-upon-Tyne, for three years.

Messrs Power Jets (Research and Development), Ltd, Whetstone, Leicester, have formed a Trade Catalogue Section in their Whetstone Library. Firms interested and associated in the production of machine tools, factory plant and equipment, physical and chemical laboratory equipment, electrical equipment, switch gear, motors, transformers, generators, etc., hydraulic pumps, air compressors, etc., who are willing to deposit a copy of their latest catalogues with Messrs Power Jets (Research and Development), Ltd, are asked to send copies of their publications to the Librarian, Power Jets (Research and Development), Ltd, Whetstone, Leicester, for inclusion in the Library.

Terminology of Interpenetrating Twins in α -Quartz

AMONG those concerned with piezo-electric applications, it would appear that there is some confusion in the terminology for describing the interpenetrating twins which occur in α -quartz. For piezo-electric purposes, the highest quality Brazilian quartz is normally used, and there are three types of twinning of importance. These are, type 1, the rotational (Dauphiné) twin, type 2, the reflexion (Brazilian) twin, and type 3, a compound twin which can be regarded as a combination of types 1 and 2. Quartz technologists have their own terms for these twins, thus the first type is termed an 'electrical twin', the other two types are broadly spoken of as 'optical twins', but their more exact descriptions are not well established.

While it has been customary to term the second type an optical twin and the third type a combined electrical and optical twin (compound optical twin), this nomenclature is sometimes, and it is thought incorrectly, reversed.

The accompanying illustrations show sections perpendicular to the trigonal (optic) axis in quartz crystals twinned respectively in each of the three ways. For clarity the sections are drawn as regular hexagons, the parent crystal completely enclosing the twinned areas (shaded hexagons). In practice, the twinning is usually irregular and often extends inwards from the outside of the crystal, but the diagrams retain the fundamental relationships, such as crystallographic orientation and electrical polarity. In each instance, optical activity is indicated by an arrow curled in the sense of rotation of plane-polarized light looking along the optic axis towards the source. Also, the parent crystal is chosen to be left-handed according to this convention. In denoting electrical polarity, the untwinned and twinned portions of the crystal are considered separately. Then the polarities marked at the vertices of the hexagons show the signs of the piezo-electric charges which would be produced at the prism edges on compression of the corresponding diameter. Finally, the lettering indicates the type of rhombohedral face occurring above each prism face, as represented by the sides of the hexagons. *R* and *r* indicate what are termed mineralogically the positive and negative rhombohedral faces respectively.

In all three types of twin, the optic axis is the twin axis. The rotational twin (Type 1) corresponds to a rotation of 60° about the optic axis without change of optical sense. Positive and negative rhombohedra are thus brought into coincidence, that is, *r*-faces of the twinned portion become parallel to

R-faces of the parent crystal and vice versa. Also the sense of polarity of the twinned material is reversed with respect to that of the parent crystal. That is, the crystal as a whole is elastically and electrically inhomogeneous, but optically it is homogeneous. It is therefore appropriate to term this an electrical twin, and obviously this type of twin cannot be detected by direct optical means.

The reflexion twin (Type 2) corresponds to a reversal in the sense of the screw about the optic axis, without any rotation about this axis. That is, the sense of optical activity of the twinned portion is reversed whereas its orientation remains uniform with the rest of the crystal. The crystal is elastically homogeneous but optically inhomogeneous, and because of the reversal of the screw axis the twinned portion is of opposite electrical polarity. It should be noted that the cause of this reversed polarity is unrelated to electrical twinning as described above. This type of twin should be regarded as a purely optical twin, but confusion can arise because of the accompanying electrical inhomogeneity. If the crystal is described as a combined electrical and optical twin it might be thought that the reference was to a combined Dauphiné and Brazilian twin, which is incorrect.

The other twin (Type 3) corresponds to a reversal in the sense of the screw axis together with a rotation through 60° about this axis. That is, it can be regarded as a combination of the first two types of twin. The crystal is both elastically and optically inhomogeneous, but there is no reversal in the electrical polarity of the twinned portion. This type of compound twin is comparatively rare.

It would seem, therefore, that the following terminology should be adopted among those using quartz for piezo-electric purposes. Type 1 should continue to be termed 'electrical twinning'. Type 2 should be termed 'optical twinning', or 'simple optical twinning' where there is any risk of ambiguity. Finally, type 3 should be termed 'compound optical twinning'.

Mechanism of the Oxidation of Coal

It is well understood that the mechanisms of the oxidation of oils¹, the curing of rubber², the polymerization of unsaturated compounds³, the overall combustion of higher hydrocarbons⁴, as well as of certain biological processes⁵, involve the formation of peroxidic bodies sometimes initiating chain reactions. Little attention has been directed hitherto to the possible role of such bodies in processes concerned with the solid phase.

The importance of the spontaneous oxidation of coal needs no emphasis, apart from fire risk, weathered coals may lose up to 15 per cent in calorific value⁶, and the coking property of gas-making coals may be destroyed. There have been occasional suggestions in the literature that the initial oxidation may involve peroxidation⁷, but so far as we are aware, no serious attempt has been made to investigate the matter. Recently we have adapted Yule and Wilson's method of estimating peroxygen⁸, for the purpose of studying the behaviour of typical coals during oxidation, and the results have proved informative.

At room temperature, finely divided fresh coal accumulates peroxygen on exposure to the atmosphere, a maximum content being reached after several weeks; this may amount to 60×10^{-6} gm. per gm. of coal. At higher temperatures its rate of formation progressively increases, but above 80°C . the maximum ultimate content falls owing to decreasing stability. Experiments with some six coals have shown known ease of weathering to fall into line with degree of peroxidation.

If previously exposed coal be heated above 80°C . in an inert atmosphere, the breakdown of peroxygen can readily be followed. Further, whereas a suitable finely ground fresh coal will ignite spontaneously in oxygen if rapidly raised to a temperature of c. 135°C ., a similar specimen, if subjected to such a preheat treatment, will not ignite.

It is well known that the attainment of a temperature of 85°C . in stored coal is dangerous; above it, oxidation becomes autogenous and there is serious risk of fire⁹. In our experience the oxidation mechanism changes at about this temperature. Below it, a relatively high concentration of peroxygen is formed, little oxygen entering into the coal substance and carbon monoxide preponderating in the gaseous products. Above it, the peroxygen breaks down rapidly, oxygen enters the coal substance and carbon dioxide preponderates in the gaseous products.

We are of the opinion that the peroxide material on decomposition opens the structure for further oxygen attack; and its rate of formation and subsequent breakdown may be taken as an index of the speed of overall oxidation in the temperature range in question. How far peroxidation is a surface effect, and how far an attack on specific chemical structures are matters for further investigation; the method has shown that certain carbons have the ability to form peroxygen¹⁰.

This investigation has been carried out during the tenure by one of us (R. E. J.) of the Institution of Gas Engineers Research Fellowship.

Phase-retarding Areas

THE phase retardation provided by evaporated fluoride films on transparent plates, suggested by E. H. Linfoot¹ as being of possible use in phase contrast microscopy, finds an important application in interferometry, where the phase-retarding areas have to be of much larger dimensions than are involved in phase contrast microscopy or applications of the Zernike test. It forms the basis of a method, developed here some time ago, of distinguishing between under- and over-correction of the aberrations corresponding to

Fig. 1.

the pattern of interference fringes observed while using the Hilger lens-testing interferometer.

Where visual use alone is of importance, the sign of the wave deformation impressed by the lens *L* in Fig. 1, relative to the plane wave reflected by *PP*, is readily obtained by exerting a gentle pull on the cables *R1* or *R2* controlling the to-and-fro movement of *PP*. When a photographic record of the performance of a model lens is required, this method is not available. We have therefore inserted at *AA*, as shown, a plane parallel plate bearing on one face a cruciform fluoride-coated area (see inset diagram). A suitable film thickness may be deposited by continuing the evaporation for a little more than twice as long as the normal evaporating time for producing a non-reflecting film. Due to the double passage of the light through the plate *AA*, such a fluoride film impresses upon the light passing through it a phase retardation of approximately $\lambda/4$ relative to light transmitted by the uncoated areas. As a result, the fringes seen are displaced by quarter of a fringe where they are crossed by the fluoride-bearing area, the displacement being in an inwards direction when the wave-front distorted by passage through the lens *L* is concave towards the eye at *E*, and in an outwards direction when the wave-front is convex towards the eye. Typical examples of interferograms are shown in Fig. 2, at (a) without the fluoride-coated plate, and (b) with the plate in position. The inward dis-

Fig. 2.

placement of the fringes along the lines XX in 2(b) shows that the wave surface distorted by the lens L in this case is concave towards the eye at E .

Other arrangements are possible. For example, the film may be formed on a surface of the diagonal DD ; or in place of a cruciform coated area on one side of a plate, there may be used what is, in some respects, a preferable arrangement, namely, a clear area on each side of a plate carrying a normal amount of fluoride to produce a non-reflecting film, the two areas being similarly situated, so that light travelling in the arm of the interferometer including PP either traverses four thicknesses of film or none.

Rotational Analysis of the S_2 Band Spectrum

THE most complete vibrational analysis of the S_2 bands lying between $\lambda 2300$ and 6200 Å. has been given by Fowler and Vaidya¹. They agree with the perturbations of the $\Delta G'$ values found by Christy and Naudé².

This irregular behaviour of the $\Delta G'$ values of the S_2 molecule no doubt complicates the rotational structure of the bands considerably. Olsson³, however, seems to have succeeded in obtaining a satisfactory rotational analysis of the (3,2), (2,2), (3,3), (2,3), (1,3), (2,4) and (1,4) S_2 bands in absorption. It appeared to be of great value to verify Olsson's analysis by analysing the S_2 band spectrum obtained in emission. Seeing that it is possible to carry out the analysis with greater accuracy in emission, it was hoped to obtain more accurate information about the observed perturbations of the $\Delta G'$ values.

The S_2 bands lying between $\lambda 440$ and 4950 Å. have been photographed in the fourth order, and the bands lying between 4950 and 6200 Å. have been photographed in the third order of the 21-ft. Gale concave grating mounted according to Paschen in this Institute. The dispersion obtained amounted to about 0.6 Å. per mm. in the fourth order and to about 0.8 Å. per mm. in the third order. The positive column of an inverted II-tube constructed of 'Pyrex' glass and fitted with large cylindrical electrodes was used as light source. The sulphur was purified by slowly redistilling flowers of sulphur four times *in vacuo* from one 'Pyrex' vessel to the next by means of an electrical oven. The final 'Pyrex' recipient was sealed on to the capillary tube joining the electrodes of the II-tube during the distillation. The light from the capillary tube passed through a quartz tube with sealed-in clear window. The quartz tube was sealed on to the 'Pyrex' tube with white sealing wax. The window was kept clear by constantly heating it with a small gas flame. The 'Pyrex' tube was first evacuated to a pressure of about 10^{-5} mm. of mercury. The sulphur in the side tube was heated to about 170° C. The discharge between the electrodes was maintained in pure sulphur vapour by a 5-kVA. 220–12,000-volt step-up transformer. Thus an S_2 light source was obtained which was very intense in the capillary tube and which could be photographed end-on through the quartz window.

The (1,14) band with its head at 4433.6 Å.; (1,15), at 4565.2 Å.; (2,16), at 4610.2 Å.; (2,17), at 4747.6 Å.; (3,17), at 4651.3 Å.; (3,18), at 4790.8 Å.; and the (3,19), at 4937.2 Å. were photographed in the fourth order of the grating. The iron arc was used to supply the comparison spectrum. Using Eastman 33 plates, the exposure time required for all the bands except the (3,19) band was about two hours with a current of 18 amp. passing through the primary of the transformer. The (3,19) band required an exposure time of about twenty hours on Eastman IIIF plates.

The plates were measured correct to 0.001 mm. on a large Abbé-type comparator built in our Institute. The wave-lengths of the iron lines were obtained from Harrison's M.I.T. Wave-length Tables. The wave-lengths of the sulphur band lines were converted to wave-numbers *in vacuo* by using Kayser's "Tabelle der Schwingungszahlen".

Practically all the stronger lines of favourably situated bands, such as the (3,17) and (3,18) bands, could be accounted for by six branches. These six branches could be identified as R_1 , R_2 , R_3 , P_1 , P_2 and P_3 branches corresponding to a $^3\Sigma_u^- \rightarrow ^3\Sigma_g^-$ transition.

The $\Delta_2 F_1$ values of the $v' = 1, 2$ and 3 vibrational states were found to agree within experimental error with those computed from the wave-numbers of the branches observed by Olsson. From the agreement of the $\Delta_2 F_1$ values obtained in the present analysis in emission, it became clear that an accuracy up to one in two million had been reached, and that the accuracy was greater than that obtained by Olsson in absorption.

The values of B'_v and B''_v could be obtained graphically from the $\Delta_2 F''_2$ and $\Delta_2 F''_2$ quantities of the various states and thus B_e and r_e could be found. These values are given in the accompanying table.

v'	B'_v	B''_v	
27	0.2502 ± 0.0001 (Naudé)		
25	0.2539	"	
24	0.2556	"	
23	0.2568	"	
22	0.2589	"	
19	0.2635	"	B''_v (extrapolated) = 0.2947 cm. ⁻¹ .
18	0.2651	"	
17	0.2666 ± 0.0002	"	$B''_v = 0.2955$ cm. ⁻¹ .
16	0.2681 ± 0.0001	"	$r'_e = 1.893 \times 10^{-8}$ cm.
15	0.2700	"	
14	0.2716	"	$\alpha'' = 0.0016$ cm. ⁻¹ .
8	0.2819 ± 0.0002 (Wilson)		
7	0.2834	"	$D'' = -19.6 \times 10^{-8}$ cm. ⁻¹ .
4	0.2885	" (Olsson)	
3	0.2896	"	
2	0.2915 ± 0.0001	"	
v'	B'_v	B''_v	
7	0.2085 ± 0.0002 (Naudé)		
6	0.2102 ± 0.0001	"	$B'_v = 0.2219$ cm. ⁻¹ .
5	0.2102	"	
4	0.2150	"	$r'_e = 2.184 \times 10^{-8}$ cm.
3	0.2129	"	
	0.2136 (Olsson replotted)	"	$\alpha' = 0.0018$ cm. ⁻¹ .
2	0.2175 ± 0.001 (Naudé)		
	0.2177 (Olsson replotted)	"	$D' = -23.1 \times 10^{-8}$ cm. ⁻¹ .
1	0.2205 ± 0.0001 (Naudé)		
	0.2200 (Olsson replotted)	"	
0	0.221 ± 0.001 (Wilson)		

The B'_v and B''_v values obtained from the partial analyses of the (4,19) band with head at $\lambda 4842.2$; (4,22), at 5309.9 ; (5,22) at 5193.7 ; (5,23), at 5359.7 ; (6,23), at 5249.8 ; (6,24), at 5418.7 ; (6,25), at 5596.1 ; (7,25), at 5472.5 ; and (7,27), at 5840.2 Å. are also included in the table. The B''_v , B''_v , and B'_v values included in the table were obtained from an unpublished M.A. thesis (1941) of Mr. F. J. Wilson of the University of Saskatchewan, Saskatoon, an extract of which was kindly sent to me by Prof. G. Herzberg. The B''_v , B''_v , and B'_v given in the table

were obtained by Olsson. The values of B'_3 , B'_2 and B'_1 given by Olsson differed from those found by me, although the $\Delta_2 F'_2$ values were practically the same. Olsson's $\Delta_2 F'_2$ values for the $v' = 3, 2$ and 1 vibrational levels were, therefore, replotted and are also given in the table.

A complete report on the results obtained so far will be published in the *South African Journal of Science*. The perturbations observed in the $v' = 2, 4, 6, 7$ and 8 levels are being investigated further.

Open Packing of Spheres

MR. S. E. ACKERMANN's axiom¹ that spherical lumps of coal of equal size have the same bulk density irrespective of the actual size is surely applicable to any symmetrical arrangement of such spheres, including the closest packing. The arrangement of spheres which he uses in his first calculation is symmetrical and satisfies the axiom, but is not a stable arrangement which would be attained by pouring the spheres into a box. His statement that the closest packing gives an increase in density as the size of sphere is decreased appears to be derived from an incorrect conception of what constitutes the closest packing. This is, of course, the arrangement in which each sphere touches twelve others (not eight), lines joining the centres forming a system of regular tetrahedra, and is the stable one which is taken up automatically.

Using Mr. Ackermann's nomenclature, the number of spheres per cubic foot is $n^3\sqrt{2}$, and the bulk density

becomes $\frac{\pi}{6}\sqrt{2}$, or 0.739. This relation holds so long

as the spheres are small compared with the dimensions of the container. A smaller density will obviously result if there are spaces nearly but not quite large enough to accommodate further spheres, and which are of the same order of dimensions as the container. Such a condition applies to the later examples quoted by Mr. Ackermann, but the results obtained even with the true optimum packing are obviously specific to a 10-in. cube and are not, therefore, of general application.

Human Chromosomes

In the last few years chromosome studies have made great progress both in theory and in methods. These methods are, however, little known outside genetical laboratories.

The application to human chromosome studies of the techniques developed in cytological laboratories has been a particularly useful complement to the histology of bone marrow, and its relations to normal and pathological haemopoiesis. The results of this kind of work in haematology have been partly published^{1,2}, and the detailed morphology of human chromosomes is at present under investigation.

The accompanying photomicrograph from a slide made by the acetocarmine squash method³ shows a metaphase plate in a mononucleated bone marrow cell obtained by sternal puncture.

So far as I am aware, no photomicrograph of human chromosomes as detailed as those obtained by such a method has been published.

Distribution of the Rh Factor in Indians

DURING the course of an inquiry into the incidence of haemolytic anemias in Bombay, it became evident that although a mild form of jaundice was common in the new-born, erythroblastosis foetalis was not encountered in any of the 3,000 consecutive labour cases admitted to the Nowrosjee Wadia Maternity Hospital during the last six months. We were therefore interested in studying the distribution of the Rh factor in Indians. Bloods from 100 Indians were tested against known human anti-Rh sera (technique Taylor¹). The results are tabulated below:

	O		A		B		AB		Total
	Rh+	Rh-	Rh+	Rh-	Rh+	Rh-	Rh+	Rh-	
Hindus:									
Male	12	-	13	-	9	-	4	-	38
Female	12	-	11	-	6	-	3	-	32
Muslims:									
Male	-	-	1	-	-	-	1	-	2
Female	1	-	-	-	1	-	1	-	3
Parses:									
Male	1	-	6	-	1	1	-	-	9
Female	2	-	-	-	2	-	1	-	5
Christians:									
Male	-	-	1	-	-	-	-	-	1
Female	5	-	1	1	3	-	-	-	10
Total	33	-	33	1	22	1	10	-	100
British:									
Male	7	1	6	1	1	-	-	-	16

Bloods from 16 British persons were tested by the same technique to ensure that the anti-*Rh* sera had not deteriorated during transit. Two out of 16 bloods were found to be *Rh*- as anticipated.

These results are reported because of the growing interest in the hæmolytic diseases of the new-born and the findings of Greval and Chowdhary² as well as of Das Gupta³ from the same laboratory that 10 per cent of Indians tested by them were *Rh*-. We believe that the difference between our results and those of other workers in India may be due to the fact that they have been using sera (after suitable dilutions) of animals immunized with red cells of rhesus monkeys. Such immunization leads to the development of anti-*Rh* as well as other agglutinins to a variable extent. It is not certain that the titre of the anti-*Rh* agglutinin is higher than that of other agglutinins in all cases. We believe, therefore, that a dilution of the immune animal serum to any particular extent (without known *Rh*+ and *Rh*- human bloods as controls) is not a justifiable procedure for determining the incidence of the *Rh* factor in any given population. We would recommend the use of immune animal sera which have been absorbed with known *Rh*- red cells for this purpose. Forty-four bloods out of the above hundred were tested with absorbed immune guinea pig serum and gave results identical with those obtained with human anti-*Rh* sera.

In the above series, none of the seventy Hindus tested showed an *Rh*-. One *Rh*- person was found among the fourteen Parsees and one among the eleven Indian Christians. The Hindus constitute 85 per cent of the labour cases in the Maternity Hospital. These findings may suggest interesting anthropological problems. A detailed report of the investigation will be published elsewhere.

We are deeply grateful to Prof. R. A. Fisher for his interest in this work, to Dr. George Taylor, Galton Serum Unit, Cambridge, for the gift of dried human anti-*Rh* sera and to Dr. Janet Vaughan for bringing them to us. We are indebted to the authorities of Nowrosjee Wadia Maternity Hospital and to Major P. Warmold, for facilities in collecting blood samples.

Influence of Sodium Chloride on the Formation of Melanin

VARIOUS widely differing diseased states with two features in common, melanuria and decreased blood sodium chloride, have been reported¹. The inhibiting effect of ascorbic acid on the formation of melanin from tyrosine, 3:4-dihydroxyphenylalanine and adrenaline is well known²⁻⁵. It is also known that the oxidation of ascorbic acid is inhibited by sodium chloride⁶.

The oxidation of tyrosine, 3:4-dihydroxyphenylalanine, tyramine and adrenaline to melanin by tyrosinase, and in the case of 3:4-dihydroxyphenylalanine non-enzymatic oxidation, in the presence of uniform concentration of ascorbic acid but with two different concentrations of sodium chloride, has been

investigated. Substrates have been used at an arbitrary strength of 0.02 per cent; ascorbic acid at the physiological strength of 0.0012 per cent⁷; sodium chloride (a) physiological, 0.9 per cent and (b) 0.5 per cent. In the first two experiments the solutions were adjusted to pH 7.4 with sodium bicarbonate; in the remainder the solutions have been prepared in phosphate buffer electrometrically determined at pH 7.42. Potato tyrosinase has been used throughout.

In the first six experiments the rates of oxidation were estimated by naked-eye comparison of the coloured products. All showed accelerated melanin formation in the solution with the smaller concentration of sodium chloride. Fifteen experiments were carried out in the Warburg apparatus. Again all showed increased rate of oxidation in the solution containing the smaller percentage of sodium chloride. The probability of twenty-one results in the same direction being due to chance is 1 in 1,048,576. The average increase of oxygen uptake by the solution containing 0.5 per cent sodium chloride was 6 per cent, which is a small value in view of the fact that the estimated error of the manometric method is about 2 per cent⁸. Though the statistical significance of these results is beyond doubt, a confirmation by a more delicate method seemed desirable. It was noted that the difference was most marked when dilute enzyme was used, that is, when the conditions approached nearer to the physiological. But dilute enzyme necessarily prolongs the experiment, and it was found that after two and a half hours the risk of bacterial contamination arose. No method of sterilization of the reacting fluids and apparatus being available, this method was abandoned and two experiments carried out with the absorptiometer, using dilute tyrosinase. In the first of these, after four hours, the 0.5 per cent sodium chloride solution showed an increase in oxidation products of 11.5 per cent. In the second, one solution contained 0.9 per cent sodium chloride, the other none. After five hours the solution without sodium chloride contained 25.3 per cent more oxidation products than the other. The absorptiometer is stated to be accurate to within 1 per cent, so there is no doubt as to the reality of these differences.

The above results demonstrate the influence of sodium chloride, with ascorbic acid as an intermediary, on melanin formation *in vitro*. Whether this has any bearing on the physiological production of melanin is a subject for investigation. However, it is considered that it may throw some light on pathological melanin formation. The cause of the hyperpigmentation in Addison's disease has always been a disputed question⁹⁻¹¹. The best-known theory is that of Bloch¹²⁻¹⁴, but this postulates disease of the adrenal medulla, which is by no means always found at autopsy¹¹⁻¹⁶. The following hypothesis is considered to be more in agreement with the autopsy findings in that it attributes the hyperpigmentation to destruction of the cortex. The established facts in Addison's disease are decrease in blood sodium chloride, decrease in ascorbic acid, and increase in production of melanin. It is known that when the cortical activity is diminished the sodium chloride content of the blood falls. It is suggested that as a result of this, the ascorbic acid is not so well protected against oxidation and its concentration also falls. Because of this the melanogen, whichever of the hydroxyphenols it is⁵, is more open to attack by oxidizing enzymes, and increased melanin production takes place.

I am greatly indebted to Prof H S Raper and Dr L P Kendal for valuable advice and access to the absorptiometer in the University of Manchester, and to Capt H Gruneberg for much helpful criticism. The work has been carried out with the aid of a grant from the Government Grant Committee, of the Royal Society.

Susceptibility of Grasses to Manganese Deficiency

FROM the literature it would appear that the manganese requirements of the different species of grasses has received but scant attention. In general¹, it is considered that grass is much less susceptible to manganese deficiency-disease than oats and some other crops. That such a generalization is not possible has been shown by a study during the past two years of the comparative sensitivity of various species of grasses. For this purpose, a number of different species of the commoner grasses were grown in a soil-sand mixture in opaque glass pots, the experiment in every detail being conducted in a manner similar to that in which an investigation into the susceptibility of cereal varieties to manganese deficiency had previously been made by Gallagher and Walsh². One experiment was started in 1943 and continued into the following year, the grass herbage being harvested in the autumn. In a further investigation arising out of this experiment, the comparative reaction of some different strains of cocksfoot was examined in 1944. In this experiment a soil growing an oat crop showing 'grey speck', mixed with its own volume of washed silica sand, was used.

In the first experiment the behaviour of perennial and Italian rye-grass, cocksfoot, timothy, annual meadow grass, couch grass (*Agropyron repens*) and fionn was tested. As in the previous experiments with cereals², a series of pots comprising each species were sprayed with a 1 per cent manganese sulphate solution, this treatment being repeated on a different complete series of pots in the following year, those previously sprayed being retained for observations on the residual effect of spraying. Seven strains of cocksfoot were included in the subsequent experiment, these being S 26, S 37, S 143, S 190, S 204 (all Aberystwyth strains), an Irish commercial strain (from the same sample as that used in 1943) and a pedigree strain bred at the Plant Breeding Department, University College, Dublin. Twenty plants

were grown in each pot, triplicate pots being sown in the case of each species and strain.

Perennial and Italian Rye-Grass These grasses reacted in a somewhat similar manner. A month after germination, the younger leaves developed a chlorotic appearance accompanied by severe tip-withering. This condition persisted throughout the 1943 season and was also apparent in the crop of the following year. Spraying when the chlorosis first became evident resulted in the development of a normal green colour. While in the 1943 season Italian was somewhat more severely affected than perennial rye-grass, the opposite held to some extent in the next season, the effect of spraying being particularly evident in the latter instance. No residual effect from the previous year's spraying was noticed.

Annual Meadow Grass and Fionn Both these grasses remained stunted, and no effect resulted from spraying in 1943. In the subsequent year, sprayed fionn plants were considerably greener than the unsprayed.

Timothy Five weeks after germination, these plants were noticed to have a yellow-green colour, and lesions developed on the lower leaves somewhat similar to those characteristic of 'grey speck' in oats. This condition did not become severe, the plants recovering quickly. Sprayed plants were much greener, in addition to being more vigorous, than unsprayed. The chlorosis appeared in the following crop, spraying again being effective as a cure. No residual effect resulted from the previous spraying.

Agropyron repens Early in the season a slight chlorosis accompanied by the development of small grey specks distributed over the leaf blade, and severe tip withering, appeared. Recovery from this effect took place quickly, and though in the initial stages the effect of spraying was quite obvious, later on there was no noticeable difference between sprayed and unsprayed plants. In the following season no chlorosis appeared.

Cocksfoot A month after germination, young leaves were chlorotic and yellow-green spots had developed on the older leaves. A week later, symptoms very similar to those described for 'grey speck' in wheat² had developed, the specks first appearing near the centre of the lamina though sometimes nearer the tip than the base. At first there was a tendency for these specks to coalesce lengthwise forming bands parallel to the veins, but later these bands joined, the result being a withered area across the leaf, the tip then bending over. Eventually the whole leaf withered, the final effect being similar to the end stage of 'grey speck' in wheat or oats². This condition developed to a severe extent and persisted until late in the season. Spraying with manganese sulphate cured this condition, first signs of recovery being evident a week after application. In the following season these symptoms again appeared though not so severely, no residual curative effect being obvious from the previous season's spraying. Spraying again resulted in normal plants.

While it was obvious at an early stage that the plants growing in the soil-sand mixture used in the experiments started in 1944 did not exhibit such pronounced symptoms of manganese deficiency as those in the previous experiment, a definite difference in the behaviour of the different strains of cocksfoot was nevertheless apparent. Again manganese deficiency showed as a chlorosis followed by 'grey speck' symptoms. S 26 and S 204 showed a moderate to severe attack, S 190 and S 143 a moderate, and

the other three strains a slight to moderate attack. It is worth noting that while the Irish commercial strain was severely attacked in 1943, only a slight to moderate attack ensued in 1944, and if this be taken as a basis for comparison, an idea is furnished as to the possible reaction of the other strains under more pronounced manganese-deficient conditions.

This study has, therefore, shown that different grasses react differently to manganese deficiency, further, the effect applies to different strains of at least one grass. The fact that the 1943 investigation was carried out under conditions similar to those which obtained in the previous investigations with different varieties of oats, wheat and barley² enables a comparison to be made of the relative sensitivity to manganese deficiency of these latter crops and the grasses used. This reveals that, depending on species and strain, some grasses may be practically as sensitive to manganese deficiency as the more sensitive oat and wheat varieties, and much more so than the least sensitive of these. Further research in this connexion is proceeding.

I wish to thank Dr Jenkins and Prof Caffrey for providing grass seeds, and Dr P. H. Gallagher for advice.

Induction of Heat in Spayed Female Guinea Pigs by Subcutaneous Hormonal Implants

DURING oestrus in the guinea pig, there is a relative hyperaemia at the antimesometrial border of the bicornate uterus¹, and after suitable hormonal treatment similar vascular changes have been induced in the spayed animal^{2,3}. Vaginal cornification, increase in uterine weight, and all the histological features so far recognized of a typical heat response can be elicited in spayed female guinea pigs by a simple administration of oestrogens, but the cyclic vascular change is only displayed after preliminary priming of the animals with small daily injections of oestradiol monobenzoate (0.0005 mgm for six days) followed by a large daily dose (0.5 mgm) for two days and a final injection of progesterone (0.2 mgm). We believe that this antimesometrial hyperaemia in the spayed female guinea pig is not a simple manifestation of oestrogenic activity, but only becomes evident when a hormonal balance approximating to the physiological condition of normal oestrus has been obtained. It is further significant that this antimesometrial hyperaemia is a response of the adult uterus and cannot be induced in the immature guinea pig by either oestrogenic⁴ or gonadotropic⁵ stimulation.

The method of hormonal administration by the subcutaneous implantation of pellets, introduced by Deansley and Parkes⁶, seemed to us to offer an attractive labour-saving alternative to the daily injections, by which the animal would receive a small but continuous dosage with the minimum disturbance.

One 2 mgm oestradiol pellet was inserted subcutaneously by means of a large intravenous needle

in each of twelve adult spayed guinea pigs. Invariably the vagina opened on the third day following the insertion of the pellet, and maximum cornification of the vaginal smears occurred on the sixth day. After six days, half the number of animals were given a subcutaneous injection of 0.2 mgm progesterone, and the other half were similarly treated on the twelfth day. The animals were killed three hours after the progesterone injection. In every case the uterus was enlarged and oedematous, with a thickened endometrium showing tortuous glands here and there dilated with secretion. These oestrous reactions were particularly well marked in the 12-day group of animals. There was, however, never any antimesometrial hyperaemia—a constant feature of the guinea pig uterus during normal oestrus. In an odd uterine section of the 12-day group a localized hyperaemia could be seen on one or other side or at the mesometrial border. We had apparently failed to obtain the necessary hormonal balance to promote the normal vascular change.

It is reasonable to assume that the inevitable fibrous encapsulation of the pellet would impose a decreased rate of absorption. At first there would be a fairly constant rate of absorption with a dosage too high for priming, and then a downward gradient, finally flattening out to a reduced dosage-level. Some such absorption curve is also suggested by Folley⁷. In the normal cycle, on the other hand, oestrogenic activity rises from minimum to maximum, to attain its peak around ovulation time. The priming dose of 0.0005 mgm in our former experiments² did not produce vaginal opening until the sixth day, and was then followed by large doses. Because of its more gradual, more prolonged and culminating high level of oestrogenic stimulation, this method, we believe, conforms more closely to the physiological gradient of hormonal activity during the oestrous cycle.

It can therefore be concluded that (a) the pellet method can provoke all the well-known vaginal and uterine reactions. It cannot, however, elicit the cyclic vascular change (antimesometrial hyperaemia), which provides a particularly delicate test of the complete uterine response to stimulation, but requires for its onset a preliminary sensitization followed by a nicely balanced quantitative interplay of oestrogens and progesterone. (b) The pellet method possesses undoubted advantages where the desired effect can be obtained by the administration of hormones over a long period, for example, to feminize experimentally the plumage growth of the brown Leghorn capon, physiologically to induce lactation in the cow, and clinically in the treatment of infantile uterus.

We have to acknowledge our thanks to Messrs British Schering, Ltd., and also Organon Laboratories, Ltd., for kindly providing us with supplies of progesterone and fused oestradiol pellets respectively.

MATHEMATICS AT THE NATIONAL PHYSICAL LABORATORY

THE National Physical Laboratory is proposing to extend its activities by the establishment of a Mathematics Division. It may be of interest to sketch the scope of the project as it is at present planned, though the plans may, of course, be modified in the light of growing experience.

The general aim may best be described by an extract from the report of an Interdepartmental Technical Committee recently appointed to consider the advisability of setting up such an establishment. This Committee decided that there is a strong case for an organization which would (1) undertake research into new computing methods and machines, (2) encourage the development of new computing methods and instruments and the dissemination of knowledge of them and of existing methods, (3) deal with problems arising from statistical science, in particular by assisting in the application of statistical methods to research, development and production problems in industry and to problems arising in the physical sciences and engineering, and by research into new statistical techniques, it would in general exclude economic, sociological and biological statistics from its purview, (4) advise on the need for new mathematical tables, and, if necessary, prepare them, (5) provide computing services for Government departments and industry, (6) act as consultant on mathematical matters to Government departments and industry.

The Committee recommended that the National Physical Laboratory should undertake these duties, and with the view of doing so the Mathematics Division is being established. It is proposed at first to organize it in three sections, concerned respectively with computations using existing machines, with statistics, and with work of the differential analyser type, including the construction of new types of machines.

For the computing section there will be a full range of modern calculating machines, including the punched-card type, and very likely new machines may be developed for specialized purposes. There will be a comprehensive library of mathematical tables. Any spare time of the section will be devoted to the tabulation of functions of general utility.

The second section will be concerned with statistical methods and their use in industry. The methods of 'quality control' of production are now well established in industry, and at the practical levels can look after themselves, but there is room for much work in a general oversight of the subject, and in the further study of data provided by 'Q.C.' records. There is also much scope for the use of statistical methods in the planning of experiments in physics and engineering in the same way as is already well established through the work of Fisher and others in the biological sciences. It is not contemplated that the work of the section should extend into biology or sociology, as this would enlarge its scope out of all proportion, and would bring it into fields which are inappropriate for the National Physical Laboratory.

The third section will deal with work using what may be described as analytical engines, including the differential analyser and other machines both existing and awaiting invention. From progress already made elsewhere in such matters, it is certain that this field is capable of great developments, but it

is more difficult to predict in what directions they will lie.

In setting up a Mathematics Division there is no intention of supplanting other existing activities. There are already in the Government service a number of mathematical groups fulfilling important specialized functions, for example, the Nautical Almanac Office. These will continue to work as before, but the new Division should be able to provide service for them by advising on their methods and perhaps assisting them in times of pressure. So too there will be no supersession of industrial work in mathematics, but it is intended that there shall be close co-operation. This should encourage the development inside industry of the use of mathematical methods, which recent experience has undoubtedly shown to be of the greatest value.

BRITISH LIBRARY OF POLITICAL AND ECONOMIC SCIENCE

THE annual report of the British Library of Political and Economic Science, which is housed in the London School of Economics and Political Science, for the year ended July 31, 1944, includes a retrospect of 1933-44. In this ten years the Library added 104,450 bound volumes to its shelves, and 154,368 cards to its author catalogue. During 1934-35 the Library added to its shelves 4,549 treatises and was receiving currently 3,339 periodical titles, as against 5,445 treatises and 4,506 periodicals in 1938-39, the last year of normal working. In the years immediately preceding the War, much was done to strengthen the staff and to improve its status. This larger and more highly qualified staff enabled the whole of the administration of the Library to be reorganized and the services to be greatly improved.

The survey is largely one of the work of 1934-39. Intensive efforts were made with much success to set up an international library truly representative of the social sciences. Many complete sets of important periodicals were secured, and gaps filled in existing sets. A new system of combined work-card and draft-catalogue-card was devised to eliminate wasteful routine tasks, and, in conjunction with a new arrangement of accession registers, was used to enable the Library to check its intake by country and by subject. A revision of the existing catalogue was undertaken, and after nine and a half years intensive work has at last been completed. With regard to cataloguing the uncatalogued material, all the non-official periodicals and almost all the official periodicals held by the Library have been included, 12,732 old pamphlets have also been catalogued, although many times that number still await attention, and 5,482 non-serial official publications have been catalogued and entered in chronological sequence under the issuing department of the relevant Government. In addition, 4,852 cards have been entered for treatises discovered to be in the Library but not in the catalogue. The separate catalogue to the Edward Fry Library of International Law has been revised and some 5,000 duplicate entries inserted in the main catalogue.

One of the many real needs of the Library is an adequate catalogue room to hold not only the rapidly expanding catalogues, but also adjacent thereto a much larger collection of bibliographies and works of reference. The principal stacking problem has been that of space. Reviewing the improvements made in

the housing of readers and the staff of the Library, the survey points out that these improvements led to a heavy increase in the use of the Library. At the conclusion of the War the number of readers wishing to consult the Library's international collections in history, politics, government, economics, law and international law, will undoubtedly present the Library Committee with an anxious and difficult task. A little is being done to improve the lending library established for undergraduate students. The seminar collections, like the present lending library, are too small, and those systems should be developed into real ancillary libraries. The physical damage suffered by the Library and its collection through enemy action has so far been negligible, and despite many changes in the Library staff, which has now only six members who are fully conversant with its activities, work is being carried on in the same spirit as in 1940-41.

According to the annual report for the year ended July 31, 1944, 1,675 works, 1,000 pamphlets, 206 non-serial official reports, excluding British Parliamentary Papers and Public Documents of the United States, were added to the Library, which on July 31, 1944, was receiving currently 2,457 annuals and 1,340 periodicals. It is a subscribing member of twenty-six learned societies. All British Parliamentary Papers are received regularly by the Library, which is also a "library of deposit" for the Public Documents of the United States. The total number of bound volumes now in the Library is 258,360.

CHEMICAL EDUCATION

At a joint meeting of the London Sections of the Royal Institute of Chemistry and the British Association of Chemists, and of the London Area Section of the Association of Scientific Workers, held in London on February 21, a spirited discussion on "Chemical Education" took place. The chair was taken by Dr G. L. Riddell, chairman of the London and South-Eastern Counties Section of the Royal Institute of Chemistry.

Various aspects of the subject were introduced by different speakers. Dr J. R. Nicholls gave his views on the knowledge and skill expected from an analytical chemist. He stressed the need for training in fundamental chemistry and in the principles underlying the various analytical procedures. Speed and accuracy are essential and keen powers of observation are required. He suggested that chemical education should include some account of the factors which determine whether a particular chemical reaction is suitable for use on a large scale, and concluded by regretting that there are no chairs of analytical chemistry at British universities and no academic schools of research in analysis.

Dr F. W. Stoye discussed the requirements of a work's chemist. He said that too high a degree of specialization in a degree course should be discouraged. At the same time, efforts should be made to give students an idea of the similarities and differences between laboratory and works practice by occasional visits to factories. After employment, the graduate chemist should supplement his academic training by courses in technology and ancillary subjects such as costing, factory legislation, etc. He should attempt to improve factory technique while making due allowance for the craft of the operative.

Mr F. A. Robmson spoke on "What is Expected of the Research Chemist". He is of the opinion that the primary requirement is a sound grasp of the principles of scientific research and, secondly, an ability to apply these to whatever problems are encountered. He must also be gifted with a healthy scepticism, inventiveness, patience, the ability to read intelligently and an interest in the utilitarian aspect of his work. The latter quality is, perhaps, most neglected in a university training, and might be fostered by informing the student of technological as well as academic discoveries.

Dr J. Kenyon, speaking on university training, pointed out that chemistry is a wonderful blend of craft and science, and that the training of the chemist is, therefore, twofold in character. In the laboratory the aim is to acquire manipulative skill and develop powers of observation and deduction, while in the lecture room the fundamental principles of the science are acquired. He stressed the importance of the latter, stating that he does not conceive it to be the function of university training to produce youthful specialists ready to fulfil the specific requirements of any particular industry. Its function is rather to supply young men and women capable of applying the results of their training—a skilled hand, an observing eye, a well-stored mind, a critical judgment and a logical intellect—to meet the varied demands of chemical industry.

Dr A. J. Jinkings spoke on the technical training of the chemist. He affirmed that full-time day courses at a university or technical college are somewhat academic in character and that emphasis is rightly placed on principles rather than on applications. Greater co-operation is needed between the universities and technical colleges, and more technical college courses should be regarded as adequate qualifications for a degree. He suggested that a faculty of technology in the University of London and a national technological institute to grant degrees and to co-ordinate and supervise technical training generally would be of outstanding value.

Dr E. A. Rudge paid high tribute to the sterling qualities of the part-time graduate, who, he said, stands high in industrial value. Against the advantages he shows in training and experience, however, are serious disadvantages of narrowness in outlook, since he lacks the experience of academic life. He suggested that this could be overcome by wider provision for part-time day classes which should be integrated, where possible, into the academic course.

The discussion which followed was summarized by Dr C. G. Anderson. A number of contributors said that during university chemical courses a certain amount of technological training and some knowledge of standard forms of plant should be given, so that graduates should not be completely at a loss on entering industry. This training would be helped by interchange between industrial chemists and university teachers, by works visits and vacation employment in industry. Training should also be given in the use of literature. Students should be given some idea of the conditions, requirements and possibilities in industry in order that they may select, to some extent, the type of work for which they are fitted. More attention should be paid to inculcating the scientific outlook quite early in ordinary school training. Part-time evening study, while valuable, is too strenuous, and more day training and State bursaries for full-time study are desirable. The opinion was expressed that there should be refresher courses

in a variety of subjects, and courses for the training of laboratory assistants and stewards, also that industry should provide special training, and apprenticeship schemes for juniors might prove of great advantage

FLAGELLAR MOVEMENTS

THE mechanics of flagellar movements and the swimming of aquatic micro-organisms form a subject of great complexity, towards an understanding of which A. G. Lowndes (*Proc Zool Soc*, 114 (111), 325, 1944) makes a critical contribution in respect of *Monas stigmatica* Pringsheim, *Peranema trichophorum* (Ehrbg.) Stein and *Volvox* sp., and at the same time effectively refutes several statements about this process that have made their appearance in standard text-books of biology

M. stigmatica is exceptionally sensitive to light, and although it swims actively and rapidly in subdued daylight, exposure to the light of an ordinary electric bulb induces a cessation of normal swimming. This, coupled with its high rate of movement, makes observation on, and photography of, flagellar movements and swimming difficult or impossible. Direct observation showed a maximum rate of swimming of 0.260 mm. per sec., that is, more than forty times its own length per sec., but observations of flagellar movement at this rate of swimming were not possible. When the rate of swimming is reduced to about one twenty-sixth of normal, the long flagellum (about two and a half times the length of the cell) is held out in front of the organism, and waves which originate at its base pass regularly along it, at the same time a current is set up in the water, and this flows in the opposite direction (that is, tip to base) and past the anterior end of the organism. This is the condition of the long flagellum when the organism is moving slowly, and in the normally slow-moving *Peranema* the flagellum is also held extended in front of the cell with the anterior end of the flagellum vibrating. Stimulation causes the whole flagellum to beat violently, but this does not bring about an acceleration in the rate of movement of the cell. Instead the organism ceases swimming momentarily, and then changes its direction of movement. Hence statements that *Peranema* exhibits a slow forward movement during which undulations of the flagellum are confined to its anterior end, and a rapid movement accompanied by undulation along the whole length of the flagellum, appear to be incorrect.

Experiments with a physical model, for example, a leather thong rotated under water, show that it is possible to propel from base to apex (that is, from the attached to the free end) of the thong a series of waves of decreasing amplitude and wave-length. With the thong all the energy is applied at one end, but with a flagellum, while most of the energy may be applied to its base by the attached cell, the flagellum itself generates energy so that no decrease in the amplitude or length of waves passing along it need occur. Increasing the speed of rotation of the thong causes it to swing from side to side, and it may finally twist up, but shortening it increases its stability. When two thongs are attached to the arms of a Y-tube which is itself attached to a spindle and the whole rotated rapidly under water, the thongs bend outwards, and if the spindle moves forward the thongs bend backwards. If, however, the spindle is rotated relatively slowly, a current of water is caused

to flow towards the base of the thongs and at this rate of movement the thongs do not bend outwards.

In *Monas*, when the swimming is slow, the flagellum is extended forward, but if the movement is rapid the long flagellum bends and trails behind the cell and causes the organism to gyrate and rotate. It is probable that in other fast-moving organisms the flagella trail behind and are not extended in front of the cell as they are in slow-swimming types. In *Volvox*, a slow-moving cœnobia alga, the pairs of cilia remain fully extended and each pair draws a current of water towards the surface of the cœnobium, but the precise contribution that these currents make towards the movement of the *Volvox* colony is not clear.

L. G. G. WARNE

FOOD IN HOSPITALS

AN interesting article in the *Lancet* (61, Jan 13, 1945) discusses the monotonous, badly cooked and often scanty menus provided by hospitals. The fault lies, the writer concludes, not only with the hospitals, which fail to appreciate the importance of correct feeding and, in most instances, to employ a single experienced food officer with sufficient influence over the hospital's income, but also with the medical men, who do not insist that their patients' needs are properly met.

The quantity of food in hospitals is often insufficient and it has to be eaten in a hurry, for the nurses have to be getting on with the next job. The medical man could criticize the arrangements on all these grounds, and he should do so, paying special attention to the quality of 'light diet', when it is ordered. The blame has to be distributed between the hospital steward, the matron, the cooks, the out-of-date kitchen equipment, the methods of preparing, carving and serving the food, its transport along draughty corridors on unheated trolleys with delays, wilful or inevitable, on the way, and so on. The solution of this problem requires, the writer concludes, a more unified control. The prescription of diets is, and must remain, part of the treatment, the ward sister, who knows her individual patients' likes and dislikes, should interpret the prescriptions, but the buying, cooking and distribution of the food should not be done by three separate officers. Further, adequate meals should be provided throughout the day, inexpert buying and failure to use the open market should be eliminated, sufficient skilled kitchen staff should be provided, and the kitchen should have modern equipment and labour-saving devices.

A second article (*Lancet*, 94, Jan 20, 1945) discusses the question: What is good feeding? The hospital should construe scientific knowledge of food values with the caterer's art of producing appetizing meals. Enough food of the right kind should be economically bought, properly stored and wisely cooked. Individual appetites vary, and those of sick people need special consideration. The lack of the important effects of the sights, smells and talk of the dining table can be counteracted by serving the food attractively. A third article (*Lancet*, 123, Jan 27, 1945) suggests remedies for existing faults, with instances of improvements that have been made. The writer's evident understanding of the difficulties of all who are concerned with hospital food, his sympathy with them and with the patients, and his lively style, make these articles as attractive as they are valuable.

FORTHCOMING EVENTS

Thursday, April 5—Monday, April 9

BRITISH PSYCHOLOGICAL SOCIETY (at the University College of the South-West, Exeter)

Friday, April 6

At 9 30 a.m.—Eric Farmer "Problems in the Occupational Adjustment of the Blind", M. I. Dunsdon "The Binet Test as adapted for the Blind" At 11 20 a.m.—I. Langan "Demonstration of Binet Tests for Blind Children" At 11 50 a.m.—M. B. Stott "Some Differences between Boys and Girls in Vocational Guidance" At 5 p.m.—Dr. K. J. W. Craik "Refractory Period in Sensory-motor Action", H. Himmelweit "Level of Aspiration, as related to Neurosis and Temperament" At 8 30 p.m.—Open Session for Discussion

Monday, April 9—Wednesday, April 11

SCIENCE MASTERS' ASSOCIATION (at the City of London School, Victoria Embankment, London, E.C.4) Annual Meeting

Monday, April 9

At 5 15 p.m.—Mr. C. L. Bryant "The Impact of Science on Common Thought" (Presidential Address)

Tuesday, April 10

At 10 a.m.—Dr. J. McG. Bruckshaw "Physics and Economic Geology", Mr. C. Bibby "Health Education through School Biology" At 11 15 a.m.—Sir Alexander Fleming, F.R.S. "Penicillin" At 5 p.m. (at the Ministry of Information Theatre, University of London, Malet Street, London, W.C.1)—Film Show and Discussion, Mr. Arthur Elton "The Scope and Limitations of the Science Teaching Film"

Wednesday, April 11

At 10 a.m.—Mr. F. W. Cuckoo "The Electron Microscope" At 11 15 a.m.—Mr. R. Matland "The Chemistry of Plastics" At 2 p.m.—Discussion on "The Role of Science in the Future Educational System" (Opening speakers: Mr. A. W. Wellings and Mr. D. H. J. Marchant) At 5 30 p.m.—Mr. J. G. Crowther "The Social Relations of Science" (Science and Citizenship Lecture)

Monday, April 9

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Ian R. Maycock "Aircraft Salvage and Repair"

Tuesday, April 10

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1 30 p.m.—Prof. B. Zaborski "The Population of Poland"

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield 1), at 6 30 p.m.—Dr. D. W. Davison "Some Crystallographic Effects in Metals"

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 30 p.m.—Mr. E. Holloway "Notes on the Rotifers of the Aylesbury District, with special reference to the Seasonal Variation of the Plankton Species, and Freshwater Microscopic Life in General"

Wednesday, April 11

INSTITUTION OF ELECTRICAL ENGINEERS (TRANSMISSION SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p.m.—Mr. E. W. W. Double "Distribution of Tensile Load in relation to Temperature and Sag of Steel-cored Aluminium Conductors"

Thursday, April 12

ROYAL COLLEGE OF SURGEONS OF ENGLAND (at Lincoln's Inn Fields, London, W.C.2), at 4 p.m.—Prof. F. Wood Jones, F.R.S. Robert Jones Memorial Lecture—"Some Reflections on his Teaching of Myology"

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p.m.—Mr. R. O. Ackerley "Factors Influencing the Design of Electric Lighting Installations for Building Interiors"

Thursday, April 12—Friday, April 13

INSTITUTE OF PHYSICS (X-RAY ANALYSIS GROUP) (at the Royal Institution, Albemarle Street, London, W.1)—Conference on "X-Ray Diffraction Analysis"

Friday, April 13

INSTITUTION OF CHEMICAL ENGINEERS (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 11 a.m.—Twenty-third Annual Corporate Meeting At 12 noon—Mr. F. A. Greene "A By-Way in Chemical Engineering" (Presidential Address) At 3 p.m.—Mr. H. W. Cremer and Mr. R. L. Fitt "The Siting and Layout of Industrial Works"

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4 30 p.m.—Annual General Meeting Prof. E. A. Milne, F.R.S. "The Natural Philosophy of Stellar Structure"

SOCIETY OF CHEMICAL INDUSTRY (PLASTICS GROUP) (joint meeting with the BIRMINGHAM AND MIDLAND SECTION) (at the Chamber of Commerce, New Street, Birmingham), at 6 30 p.m.—Dr. K. W. Pepper and Dr. F. T. Barwell "Fabric-Base Plastics"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

FOOD CHEMIST in the Research Department of a well-known London firm, to carry out the analysis of a wide range of food materials packed in metal containers—The Ministry of Labour and National Service Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 2722 XA) (April 14)

SENIOR LIVESTOCK OFFICER to be responsible for the Division of Animal Husbandry in the Department of Agriculture, Government of Jamaica—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3844 A) (April 17)

LECTURER IN METALLURGY, with CHEMISTRY as a subsidiary subject—The Principal, Dudley and Staffordshire Technical College, Dudley (April 18)

DRAINAGE AND IRRIGATION ENGINEER by the Gambia Government—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 950 A) (April 18)

LECTURER IN ELECTRICAL ENGINEERING SUBJECTS in the Ipswich School of Technology—The Chief Education Officer, Education Department, 17 Tower Street, Ipswich (April 20)

TEACHER OF MATHEMATICS AND SCIENCE, with duties chiefly in the Junior Building School—The Principal, Technical College, Huddersfield (April 20)

TECHNICAL ADVISER TO THE EXCISE COMMISSIONER, Government of the United Provinces, India (candidates must be highly qualified distillery technologists, specializing in biochemistry of fermentation but with sufficient knowledge of chemical engineering to advise distillers on constructional and allied problems)—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3813 A) (April 21)

LECTURER (full-time) in the DEPARTMENT OF NATURAL SCIENCE (candidates must have an Honours Degree in Zoology at a British University)—The Principal, Derby Technical College, Normanton Road, Derby (April 24)

ASSISTANT LECTURER in WEAVING—The Registrar, College of Technology, Manchester 1 (April 24)

CHEMIST AND ASSAYER in the MINING AND GEOLOGICAL DEPARTMENT, Government of Kenya—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F 3845 A) (April 28)

TUTOR in PHYSIOLOGY—The Principal, Lady Margaret Hall, Oxford (April 30)

SECOND ASSISTANT REGISTRAR—The Registrar, The University Old Clarendon Building, Oxford (May 5)

ASSISTANT REGISTRARY (full-time)—The Registry, University Registry, Cambridge (marked 'Confidential') (May 12)

LECTURER in MECHANICAL ENGINEERING—The Principal, Heriot Watt College, Edinburgh (May 14)

LECTURER in REFRATORIES in the DEPARTMENT OF METALLURGY—The Registrar, The University, Sheffield (May 14)

UNIVERSITY CHAIR of PSYCHOLOGY tenable at Bedford College—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (May 23)

LECTURESHIP in DESIGN AND ANALYSIS OF SCIENTIFIC EXPERIMENT—The Registrar, University Registry, Oxford (May 26)

ASSISTANT LECTURER in the DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Liverpool (May 28)

LIBRARIAN—The Secretary and Treasurer, University College Dundee (August 31)

TECHNICIAN in the DEPARTMENT OF ANATOMY—The Registrar, King's College, Newcastle-upon-Tyne

GRADUATE in ENGINEERING or PHYSICS to teach PHYSICS and MATHEMATICS in the Abersychan Mining and Technical Institute—The Director of Education, County Hall, Newport, Mon.

WATER SUPPLY IN GREAT BRITAIN

LAST summer, the Government issued a White Paper on water policy in Great Britain, which was dealt with, in connexion with related current discussions, in *Nature* of August 5, 1944, p 159. Since then, there have been frequent references to the subject in Parliament and elsewhere, showing that public opinion was alive to the many vital issues involved. Recently a committee of the Institution of Civil Engineers has produced a valuable "Report on the Government White Paper on a National Policy", and now the Government itself has brought before the House of Commons a Water Bill, where it was subjected to vigorous discussion.

The Bill follows closely the lines of policy indicated in the White Paper, though certain outstanding features are naturally clarified in some degree. On the administrative side, the major features are the vesting of all powers in the Minister of Health, including those which relate to surface waters as well as to underground supplies, coupled with a somewhat hesitating curtailment of the supposed right of the individual to do what he pleases with any underground water he can get. Regarding surface supplies, the intention, no doubt, is to accelerate and cheapen procedure by the substitution of local inquiry under more ordered regulations for the more costly and less fettered proceedings of parliamentary committees. Whether this aim will be accomplished may be in some doubt, in view of the fact that various bodies are given the right to object to the Minister's decision concerning the acquisition of lands and water-rights by water-undertakers, until those decisions have been ratified by Parliament.

A fundamental feature of the Bill is the important position of the Central Advisory Water Committee. The Committee is to advise the Minister (or any other Minister concerned) regarding the conservation and use of water, to consider the operation of enactments which may affect water resources and to make representations thereon, and to advise any Minister on questions relating to water which he may refer to it. Advisory powers could scarcely be drawn more widely. Unfortunately, however, the Bill gives not the slightest inkling of the constitution of this all-important body. The next clause states all too concisely that the Minister may, *by order*, make provision respecting its constitution and procedure. It is scarcely too much to say that on the constitution and working of this Committee the whole success or failure of the Bill will depend, and one might reasonably look for some guarantee that it will consist of men with the highest technical knowledge who will bring unfettered judgment to bear on problems referred to them. Through the work of this Committee the investigation of all problems of water supply in Great Britain should be organized, and the application of its conclusions to the conservation and development of water resources for all purposes should be ensured.

At the next stage, regional organization for the assessment of resources and the co-ordination of local schemes is to be promoted by the establishment of joint advisory water committees, in regions where the demand is judged to be large in proportion to local resources. This proposal is clearly to be viewed in connexion with the powers to define areas within which the right to abstract underground water is prohibited except by sanction of the Minister, for promoting voluntary or compulsory amalgamations of water undertakings, and for variation of areas of supply. In this case the general constitution, powers and duties of such joint committees are defined, and while it is reasonable (as laid down) that they shall consist mainly of representatives of the water-undertakings and local authorities concerned, it is to be regretted that there is no provision for independent scientific and technical advisers.

Further power of control is provided by clauses for the compulsory purchase of land, either for water-works or for the protection of supplies, and for the enforcement of by-laws designed to protect sources against pollution by any acts of the owners or occupiers of the land from which such supplies may be derived. In practice, this last will largely concern the protection of underground supplies, and will depend for effective application on very detailed geological knowledge to define the areas which the by-laws should control.

An examination of the Bill tends to confirm some of the doubts expressed by the expert committee appointed by the Institution of Civil Engineers in its report on the White Paper. All will agree with the committee's general commendation of the White Paper (which it would doubtless extend to the Bill) as representing a valuable step in the development of official recognition of the vital public importance of water questions. At the same time one feels that the committee has been cautiously reticent in the expression of its views, some of which would probably receive more forceful expression by the members as individuals. While modestly disclaiming its right to express an opinion on policy of a controversial nature, the committee evidently is in no doubt that the control of water should be in the hands of a single central authority, with the fullest scientific and engineering knowledge at its command, with power to formulate policy in the light of such knowledge, and to guide the development of water schemes accordingly. It is in this matter of clearly defined organization and control that the proposals of the White Paper (and the Bill) fail to show complete grip of the requirements, and betray too familiar concern for the susceptibilities of existing organizations.

Beyond this central conception, the valuable comments of the Institution's committee may be reduced almost to the single word—research. It is most stimulating to have so clear an expression, from a source of such authority, of the urgent need for more data and more study. Far more extensive records of rainfall are needed for Great Britain generally, and still more intensive studies of its wide variation within small regions. The great need for river-gauging on a well-organized plan is properly stressed,

and one readily appreciates the committee's doubts whether any such scheme would be likely to develop properly under the proposed river boards. The whole fundamental question of percolation and its relation to the maintenance of underground supplies demands far more extensive investigation than it has yet received in Britain. It is not a matter for the mere application of general principles, but for close and prolonged investigation in representative areas. The importance of the general collection and tabulation of information regarding underground water is properly stressed by the committee, which also does well to direct attention to the fact that much of the most valuable information necessary for preparing maps of underground water-levels is provided by great numbers of private wells, a large proportion of which may soon be abandoned. Their investigation, especially in regard to their seasonal variation, is therefore the more urgent.

It appears likely that the committee would feel satisfied that its views regarding such matters as the assessment of compensation water and the protection of underground supplies are reasonably met by the Bill. In general, the proposals for the collection of data regarding underground sources may be adequate, though it is still far from clear that all the information is to reach a single centre for co-ordination and study. Details of new borings are to be made available to the Geological Survey (under guise of the Committee of the Privy Council for Scientific and Industrial Research), but what is to be the fate of all the information collected by the joint advisory water committees? More especially, what must impress all who have studied the Bill, is the absence of any clear provision for the investigation of surface waters and the problems associated with them, though such sources still provide much the larger part of the water supply of Great Britain. The White Paper indicated the need for extending the work of the Inland Water Survey—though it confused the issue by stating that the Survey's most vital work of river gauging should be undertaken by the river boards. In the Bill no such matter is specifically mentioned, and one is left to hope that this and many other things may be included under the Minister's general duty to promote "a national policy relating to water".

The last of the valuable proposals by the committee of the Institution of Civil Engineers is for the appointment of a research committee to co-ordinate work relating to water problems, as it may be conducted in various Government departments, in the universities or by water undertakings. Here, surely, should lie one of the most important functions of the Central Advisory Water Committee. If that committee is constituted of men of unquestioned independence, experience and knowledge, representing the various branches of administration, science and engineering involved, we shall have every reason to hope that the good intentions which undoubtedly lie behind the Bill will really be translated into practice. Here, if anywhere, we may find the 'single authority' which should be responsible for the water policy of Great Britain.

PROBLEMS OF THE LOCATION OF INDUSTRY

CRITICISM of the Distribution of Industry Bill in the House of Commons on March 21 appeared to centre essentially on two points, which found expression in the amendment moved by Sir George Schuster but afterwards withdrawn when the Minister of Production had made a statement first, that no steps have been taken to establish a central independent tribunal to consider the national position as a whole, as recommended in the report of the Barlow Commission, and, secondly, that there has been no satisfactory implementation of the Government's intentions, as set forth in the White Paper on Employment Policy, that the Board of Trade should be suitably strengthened to undertake the new responsibilities proposed in the Bill. Sir George Schuster, in moving his amendment, made it clear that he only supported the Barlow Commission's recommendation for a central authority to review the position of the country as a whole and to make research into all those factors which affect the location of industry, in so far as such an authority stood outside the political field and was capable of an independent and objective review of the position, and of keeping it under constant survey. He did not advocate the establishment of an independent authority with large powers outside the control of Parliament, and in so far as Mr Lyttleton accepted the view that a large conspectus was required, there may be no more difference between his position and Sir George Schuster's than between the majority and minority recommendations of the Barlow Report regarding the constitution and functions of the national authority.

That difference, however, was, in effect, as to whether the central planning authority or national industrial board should be a purely advisory body, or whether a separate executive department presided over by a Cabinet Minister should be created. The need for such an authority was not in dispute. It is the reluctance of the Government to implement the recommendation that it professes to accept which causes uneasiness, and Mr Lyttleton's remarks about the impracticability of an independent authority appear to be little more than a quibble designed to cover indecision on the part of the Government. The question is essentially that of relating knowledge and action, and the fear that action may be determined by prejudice rather than knowledge underlies much of the criticism of the Distribution of Industry Bill.

There was little in Mr Lyttleton's speech to indicate adequate appreciation that much research and collection of factual data are necessary as a foundation for an effective national policy. That was Sir George Schuster's main point. All areas of Britain require consideration as part of a national plan, since all are, in a sense, development areas in this time of immense technical and scientific advance. Proper surveys are required in all regions if we are to determine our broad objectives and first steps.

Apart from the surveys in the special areas, a good deal has already been done in regional surveys. Besides the surveys of West Cumberland and of South Wales for which Colonel W. C. Devereux has been responsible and to which Mr Dalton also referred, Sir George Schuster mentioned work done by the West Midland Group in surveying the Midlands area, and a survey by a Thames-side group of industrialists. Even the more limited surveys, such as those on which the "Plan for Merseyside" is based, require linking to larger regional surveys of, for example, south Lancashire as a whole, and the failure to relate schemes such as the Tummel-Garry project or the Gairloch project prepared under the Hydroelectric Development (Scotland) Act of 1943 to an adequate national and regional planning scheme in which the location of industry is considered in relation to the utilization of national resources as a whole and not merely of water power is, to say the least, far from reassuring.

Besides these, the Northern Industrial Group, formed in 1943 to develop and promote the prosperity of existing industry generally, including the basic industries on which the north-east of England depends for the bulk of its employment, and to encourage commercial, technical and industrial research with the view of developing ancillaries to the basic industries and to attract and help to establish new industries, while sponsoring no formal surveys, has done something to elucidate the action required to prevent the recurrence of depressed areas. Its recently issued "Memorandum on the Government White Paper on Employment Policy", like its earlier memorandum, "Considerations Affecting Post-War Employment in the North-East", shows the extent to which industry itself is already prepared to advise and co-operate with the Government in respect of industrial needs and development in relation to local and national plans.

So far as the location of industry and the development of the north-east of England as a balanced unit are concerned, this latest memorandum urges that whatever administrative system is evolved by legislation in future must take all the relevant factors more carefully into account than has been done under the war-time controls. Besides urging the working out in greater detail of the application of 'negative licensing', the memorandum points out that, in framing a long-term policy, it is essential for the Government to make its decisions on policy now, so that industry may know how to plan for the future even if the date when plans can be put into effect must remain undecided. In particular, the memorandum calls for an early decision on the general policy for location of industry, transport facilities, etc. Immediate arrangements are required for more extensive factory construction in the north-east, including the reconversion of factories in the area from war to peace production, licences to build for firms who have chosen their own sites in the area, and information as to when these are likely to be granted, and the provision of adequate housing for operatives and administrative and technical staff. Existing responsibilities of the Commissioner for the

Special Areas should be transferred to the Board of Trade, and a single agency appointed to act on behalf of the Government in regard to existing or proposed Government factories or buildings, any regional organization established for dealing with the reconversion of industry should consist of Government representatives only, with full executive powers, but advised by a parallel group representing employers, employees and other interests in the area.

The Northern Industrial Group, and the more recently formed North-East Development Association, are clearly well qualified to advise in many ways any Government regional organization which may be established, but this evidence that industry is prepared and anxious to co-operate only gives greater force to the two critical conditions brought out in the recent House of Commons debate—an adequate central planning authority competent to make the broad policy decisions required, and a staff qualified to exercise the positive functions necessary to stimulate and not repress enterprise—and, it might be added, alert to check any restriction or restraint of trade masquerading under the title of development or any other catchword.

Sir George Schuster insisted on the need for some central authority to fit together the results of the regional surveys into a national survey, though he also stressed the need for liberty for all regions to develop within certain broad limits, both these points are widely enough held to represent a broad consensus of opinion. That consensus is scarcely recognized or accepted by the Government as yet, in spite of Mr Dalton's claims that the Bill represents the largest common measure of agreement in the Government itself. The need is not met entirely by the Location Planning Room which has been transferred from the Ministry of Production to the Board of Trade as a joint responsibility of the two Departments. It is true that, as Mr Lyttleton said, this valuable experiment will offer industry an information service regarding location which has never been available before, and that it will relieve industrialists of much of the burden of primary inquiries and thus facilitate decision. It is also in accord with a main recommendation in the Barlow Report. But it is equally clear from the debate that the operation and development of this planning room and all it stands for by the Board of Trade will be regarded with misgivings or scepticism by industrialists until there is evidence that the Board is being strengthened in the way that the White Paper on Employment Policy indicated.

Although Sir George Schuster pressed for central guidance, he also insisted on the need for a spirit of co-operation between industry and Government, with industry being given the information which would enable it to respond intelligently to the Government's policy and guidance. No two things would do more to secure that than evidence first, that the Government has a central policy in regard to the location of industry, with all that is involved in the related problems of the control of land use, town and country planning, agriculture, and building, and secondly, that efforts were being made to equip the Board of Trade—and other departments—with the type of Civil servant qualified by training, outlook and experience to deal with these

positive functions of government with imagination, decision and courage. By removing the fear of mere restrictionism, this second step would go far to remove the misgivings with which this first measure of control of location of industry has been received, but until the Government has offered some clear proof that it is willing and able to deal courageously and constructively with the central issues involved, no improvement in staffing of Government departments or co-operation on the part of industry will avail to avoid the wastage of national resources or the recrudescence of derelict areas in the years immediately ahead.

MODERN STATISTICAL METHODS IN INDUSTRY

Sampling Inspection Tables

Single and Double Sampling By Harold F. Dodge and Harry G. Romig. Pp. vi+106 (New York: John Wiley and Sons, Inc., London: Chapman and Hall, Ltd., 1944) 150-dollars.

Regression Analysis of Production Costs and Factory Operations

By Philip Lyle. Pp. xii+208 (Edinburgh and London: Oliver and Boyd, 1944) 15s net.

FOR about twenty years, statistical methods have been finding their way into the control of industrial processes. In the 1920's only slow progress was made against a great deal of doubt and opposition from manufacturers themselves. About 1932 the tide began to flow more strongly and increased in force as the modern methods were found to provide not merely a new way of formulating old knowledge but also a technique involving substantial saving in labour and money. The War itself has probably done more in six years than peace would have done in sixty to promote the widespread adoption of the new methods. In 1935 a few enthusiasts in Great Britain were still trying to persuade manufacturers of the power of the new tools at their disposal, in 1945 there is a division of the Ministry of Supply encouraging research in these tools and acting as the centre of an extensive network of quality control.

The volumes under review are interesting examples of the use of methods involving the theories of statistics and probability in two rather different branches of the industrial process. Mr Dodge and Mr Romig are concerned with economy in inspection of a mass-produced article and the guarantee of quality to the consumer. Mr Lyle is concerned mainly with the dissection of costs in a manufacturing plant and their relation to output and utilization of production factors.

The four Dodge-Romig tables are prefaced by what are virtually reprints of articles in the *Bell System Technical Journal* in which they were originally published. The tables have been in general demand since the outbreak of war, and their issue under one cover will be welcome.

There are two main reasons why inspection on a sampling plan is necessary in certain types of industrial process. The first is that test-inspection may destroy the sample, as for example in dealing with ammunition, the only satisfactory way of testing a round being to fire it. Secondly, the sheer volume of production and expense of inspection may make it

a physical or financial impossibility to examine more than a proportion of the output. Dodge and Romig are concerned mainly with the second class of case.

The so-called system of *single* sampling lays down a routine on the following lines: the product comes forward from the factory in aggregates known as 'lots'. A sample of specified size n is taken from each lot and examined. If it does not contain more than a specified number c of rejects, the lot is accepted in total. If it does contain more, the lot is completely inspected and rejects eliminated. The *double* sampling process is more elaborate. From any lot a first sample of n_1 is chosen. If the number of rejects does not exceed some level c_1 the lot is accepted. If it exceeds some number c_2 , the lot is inspected in full. If it lies between c_1 and c_2 a second sample of n_2 pieces is taken and inspected. If the number of rejects in this second sample does not exceed c_2 , the lot is accepted, in the contrary case it is inspected in full.

In either process there is a possibility that lots will be passed which fail to fall below some specified tolerance level. The probability that this is so is the 'consumer's risk' of getting an unsatisfactory lot. In the single-sampling tables it is taken as 10 per cent. For any specified tolerance limit and consumer's risk it is possible to find what number c should be determined as the acceptance level with a given sample size n , but either c or n is still at choice. Dodge and Romig determine those values which make the necessary number of inspections a minimum.

A further concept due to the authors is that of AOQL (or 'average outgoing quality limit'), that is to say, the average proportion defective in the material *after inspection and the replacement of rejects where inspection is carried out in full*. The single-sampling tables give this quantity and thus provide, for specified sizes of the lot, lot-tolerances, process averages (that is, population values of the proportion of rejects) and a consumer's risk of 10 per cent, the appropriate sample size n and the acceptance number c which will minimize the inspection required. The first of the double-sampling tables is on the same lines but of course specifies the two acceptance numbers c_1 and c_2 . There are two further tables of a similar character based on specified 'average outgoing quality' limits instead of lot tolerances.

The computation of the tables was no easy task, even with the help of various approximations. The values given are no doubt sufficiently accurate for working purposes, but it seems possible that the methods employed of arriving at them are capable of improvement and refinement. The whole subject furnishes an interesting field for research in practical mathematics, and in the meantime the Dodge-Romig tables continue to do first-class service to industry.

The most encouraging feature of Mr Lyle's book is that it is written, not by a statistician, but by a practical industrialist who has proved the value of regression analysis in his own field. One of the better ways of learning statistical methods is to write a good book about them, and that is what Mr Lyle has done.

In many respects sugar refining is an excellent industry on which to test and to illustrate regression analysis. The final product, perhaps the purest known to commerce, has a standard which is easily measurable. Apart from molasses, there are no other end-products to complicate the allocation of costs. The

factory operations are relatively simple, and Mr Lyle has only to consider in his main analysis of operating costs the factors of labour, fuel and factory overheads (in which he includes maintenance and renewal of machinery). In fact, sugar refining can claim to be the hydrogen atom of industrial production, the simple model exhibiting the essentials of the theory with a minimum of complications.

Mr Lyle considers in the first place a comparatively short period of forty weeks, and shows how to represent the weekly output as a linear function of the weekly cost and to test the significance of the results. He proceeds to more complicated cases by introducing further variates, including non-linear terms, and discusses the accuracy of the estimates in terms of fiducial limit bands (which for this purpose are identical with confidence intervals). He then deals with long-term changes in the production costs, has a few pages on price- and wage-levels, discusses unit costs and concludes with a number of appendixes on notation and the technique of correlation and regressive analysis. In effect, Mr Lyle shows in a most illuminating way how the statistician can take up the inquiry into production costs at the point where the cost-accountant has to lay it down.

The book is not intended as a statistical text-book but as an introduction to such a book. Nevertheless, it provides one of the best exemplifications of a particular branch of theory I have seen. In feeling his way into the subject Mr Lyle has encountered a number of practical difficulties, such as the effect of outliers on the regression line, which are apt to be glossed over in theoretical treatments. He has, quite rightly, dealt with them at some length and managed to achieve an excellent balance between theory and practice. It is to be hoped that he will be successful in his main object of "trying to interest industrial workers in a very useful subject of the very existence of which many of them are quite unaware".

M G KENDALL

THE FLORA OF THE PACIFIC STATES OF AMERICA

Illustrated Flora of the Pacific States

Washington, Oregon and California. By Leroy Abrams. In 4 vols. Vol 2. Polygonaceae to Krameriaceae, Buckwheats to Kramerias. Pp viii + 635. (Stanford University, Calif. Stanford University Press, London. Oxford University Press, 1944.) 45s. 6d. net.

THE region of the Pacific States with which the book under review deals is of great interest to the student of geographical distribution and the taxonomist. The area is peculiarly rich in endemic genera and species, and this is especially true of California. The Pacific States show interesting geographical connexions with the flora of Eastern Asia in genera, however, which are probably too recent in origin to be adduced in support of any hypothesis of continental drift, but are to be regarded rather as evidence of the similarity of ecological conditions and the high efficiency of dispersal agents, not perhaps excluding man himself. Thus the saxifrageous species *Leptarrhena pyrolifolia* is native both to the coastal regions of north-west America and to eastern Asia. Again, the genus *Pectantra* comprises five species of which three are endemic to the Pacific

University Press, London Oxford University
Press, 1942) 24s net

States, whereas the other two are natives of Japan. But it is in the endemics of the region that the chief interest of the flora rests. Some of these, such as *Romneya Coulteri*, the genera *Eschscholtzia* and *Lewisia*, are familiar to British horticulturists. In the family Polygonaceæ the monotypic genera *Gutmannia*, *Nemacaulis* and *Hollisteria* are all endemic to California while of the 150 known species of *Eriogonum* 80 are found in the Pacific States, many of them endemic. In the Crassulaceæ there are some 35 endemic species belonging to the genera *Sedella*, *Budleya*, *Stylophyllum*, *Hasseanthus* and *Gormania*. In the Cruciferae most of the species of *Thelypodium*, *Streptanthus* and *Caulanthus* are endemic. The Rosaceæ, too, provide a large number of endemics, particularly in the genera *Horseshoe* (19 spp) and *Ivesia* (17 spp). In the Leguminosæ the outstanding genera in this respect are *Lupinus*, of which 58 species are probably endemic, *Hosackia*, of which most of the 39 species are endemic, while *Astragalus* is represented by 137 species of which 83 are probably endemic.

It is obvious therefore that botanists generally will warmly welcome the appearance of the second volume of Prof. Abrams' monumental work. The first volume appeared in 1926 and dealt mainly with the vascular cryptogams and the monocotyledons. The present volume comprises the families belonging to the Polygonales, the Centrospermes, the Ranales, the Rhodales and the Rosales and contains generic and specific keys, descriptions and illustrations of 1,663 species. The figures are in general good, but some of those reproduced from Britten and Brown's Flora might well have been replaced, such as those of *Dryas drummondii*, *Lychnis coronaria* and *Rumex pulcher*, where the characteristic appearance of the species had quite evaded the artist.

The plan of the Flora and the concept of species which is adopted is very similar to that in Britten and Brown's "Illustrated Flora of the North United States and Canada." It is therefore of some interest to compare the plant populations as presented in these two works. The richness of a flora in species is related on one hand to the size of the area concerned and on the other to the diversity of ecological conditions which it presents.

Britten and Brown's Flora treats of a vast area of some two million square miles, ranging from the Atlantic to the 102nd meridian and from south Virginia to the Arctic. The Pacific States, on the other hand, comprise an area of only 323,000 square miles, but include mountains rising to an elevation of more than 14,000 ft and a southern limit that extends beyond the Tropic of Cancer. Moreover, the geology is very varied in character. It is therefore of interest to note that, even in the families with which the volume under review is concerned and which are mostly north temperate in their climatic requirements, the number of species is about 50 per cent larger than for the northern States and Canada. In the Rosaceæ alone does the Pacific State flora lag behind. In the Polygonaceæ and Leguminosæ, the Pacific States have more than double the number of species, while in the Saxifragaceæ, Papaveraceæ and Portulacaceæ there are three times as many.

All botanical libraries will no doubt wish to add this volume for its own sake, but their straitened finances will enhance appreciation of the public spirit of those through whose financial assistance it has been possible to place this work on sale at so low a price.

E. J. SALISBURY.

PROF. HUTTON WEBSTER is well known from his earlier books on "Primitive Secret Societies" and on "Rest Days." His new book, on "Taboo", collects together from ethnographical literature a mass of data concerning the ritual prohibitions found in what are commonly called 'primitive societies'. His aim, as stated by himself, is "to show how important a place taboos hold in the cultural evolution of mankind." The author's definition is as follows: "Taboos form a specific series of thou-shalt-nots. They are not to be confused (as in popular usage) with social conventions and regulations of a negative sort, conventions and regulations without an obvious utility. They are to be distinguished from restrictions resting on the vague notion of unluckiness which attaches to certain acts or things or times, restrictions found in the lower culture and, under the attenuated form of a survival, lingering among ourselves. More important still, there are innumerable prohibitions, both animistic and non-animistic in character, which must likewise be excluded from the conception of taboo if this is to possess any scientific validity and retain a place in ethnological theory. Taboos are prohibitions which, when violated, produce automatically in the offender a state of ritual disability—'taboo sickness'—only relieved, when relief is possible, by a ceremony of purification."

Prohibitions relating to the reproductive life, the relations of the sexes, death and the dead, strangers and strange phenomena, sacred persons and sacred things are dealt with in separate chapters and there are more general chapters on sin and ritual defilement, on the economic aspects of taboo and on its social aspects.

What anthropological science needs is a satisfactory general theory of taboo, or better still a theory of ritual prohibitions in general. Such a theory should enable us to understand not only the widespread existence of such prohibitions, but also the forms they take. Interesting as the present work may be as a collection of examples, it fails to make any contribution to anthropological or sociological theory. Prof. Webster regards taboos in general as arising from the fears and forebodings that beset "primitive man" in an "unfriendly world." The fears themselves "are often the product of a lively imagination and of an abysmal ignorance." Taboos "reflect", he says, "man's ignorance of his surroundings, whether natural or what we call supernatural. They are rooted in the fear of the unknown and the unknowable."

It is evident that the statement that taboos result from man's ignorance and fear does not provide any explanation. It does not, for example, give any reason for those ideas of ritual defilement or pollution which Prof. Webster himself regards as an essential characteristic of taboos.

Perhaps it is unjust to criticize the author for not doing what he does not set out to do. He has given us an extensive compilation of illustrative instances of taboos. The theoretical problem of the nature and function of these prohibitions remains just where it was.

A. R. RADCLIFFE-BROWN

RUBBERS AND THEIR CHARACTERISTICS: REAL AND IDEAL*

By DR. L. R. G. TRELOAR

British Rubber Producers' Research Association

Chemical Structure of Rubbers

NATURAL rubber, extracted from latex by coagulation with acid, and afterwards washed and rolled, appears on the market as crepe or smoked sheet. Raw rubber, as these materials are called, is essentially a hydrocarbon (C_5H_8)_n having the chemical structure shown in Fig 1. It is a polymer of isoprene, the isoprene units being joined together in the form of a long chain. The actual length of the molecular chain, or *molecular weight*, of rubber has been the subject of much discussion, estimates obtained by different methods having ranged from about 1,000 to about 500,000, and it is only within the last few years that the question has been settled. The reliable measurements of Dr G Gee show that the mean molecular weight of a typical raw rubber is about 350,000, corresponding to a chain of about five thousand isoprene units.

This long-chain molecular structure accounts for the very high viscosity of rubber solutions in ordinary solvents like benzene. We imagine that the resistance to flow is due largely to the mutual interferences and loose entanglements between these very long molecules. However, raw rubber is ultimately completely soluble, and we conclude, therefore, that the molecules are not in any way chemically joined together.

It is otherwise with vulcanized rubber, which swells considerably in solvents (to five or ten times its original size), as if it were trying to dissolve, and yet does not go into solution at all. In this case it is reasonable to suppose that the vulcanization (that is, chemical combination with sulphur) has led to a cross-linking of the molecules (see below).

Fig 1 is intended to show the diversity of chemical composition of materials which, under certain conditions, show rubber-like elasticity. Whereas most practical rubbers are built up on a chain of carbon atoms, this is by no means an essential feature, as the examples of gelatin and elastic sulphur show. The important and invariable feature of all rubbers is the pattern of their molecular structure, there is no highly elastic material, so far as I am aware, which is not built up of very long chain-like molecules.

Origin of the Elasticity

Until about twelve years ago, none of the theories of the elasticity of rubber which had been proposed could be regarded as even approximately satisfactory. Attempts to interpret long-range elasticity on the basis of interatomic forces were manifestly inadequate, and it was not until Meyer, v Susich and Valko introduced the conception of a *dynamac*, in contrast to a *static*, basis for the phenomenon that the mystery was solved. The theory developed rapidly through the work of Guth and Mark and of Kuhn, and is now generally accepted as representing the correct method of approach.

To understand the kinetic point of view we must first examine the form of a long-chain molecule, considered as an isolated unit. For this purpose it is usual to consider the simplest possible chain structure, namely, the paraffin molecule. The assumption is

Fig 1

made that the carbon atoms of the chain are in a state of continual thermal vibration, so that they may take up any relative positions consistent with the maintenance of a fixed bond-length and a fixed angle between bonds ($109\frac{1}{2}^\circ$). According to this assumption, each C—C bond may be regarded as rotating freely about the preceding bond as axis. There is chemical evidence that such rotation does take place. In consequence of this random rotation about bonds, the chain will not be a uniform zigzag in one plane, as in Fig 2a, but will assume a randomly kinked form in three dimensions, as indicated in Fig 2b. The distance between the ends of the chain in this form is likely to be very much less than the outstretched length of the molecule in Fig 2a, and the statistical treatment of the problem enables the probability of any given end-to-end distance to be calculated. The function representing this probability turns out to be the ordinary Gaussian error function,

Fig 2 PARAFFIN CHAINS (a) PLANAR ZIG-ZAG, (b) RANDOMLY KINKED

* Royal Institution discourse delivered on December 15

Fig 3 FUNCTION REPRESENTING THE PROBABILITY $p(r)$ THAT A MOLECULE HAS THE LENGTH r

which is represented in Fig 3. The normal state of the free molecule may be identified with the maximum of this curve, that is, it is the most probable state, and the corresponding length is found to be proportional to the square root of the number of 'links' in the chain.

We see, then, that if the molecule is forcibly extended, and then released the random thermal motion will rapidly restore it to a length not very different from the statistically most probable length. The molecule, therefore, exhibits elasticity. Moreover, its elastic extensibility is proportional to the square root of the number of chain links, or the molecular weight. This theory, therefore, explains in a natural manner why long-range extensibility is found only in association with chain-like molecules of very great length.

The thermodynamic development of the kinetic theory leads to some rather striking conclusions. Two of the more important of these are

(a) In rubber held at constant extension, the tension is proportional to the absolute temperature.

(b) The extension of rubber takes place without change in its internal energy, hence there is an evolution of heat equal to the work done on the rubber by the stretching force.

In these two respects the behaviour of rubbers is closely analogous to that of a gas. The agreement with experiment which is found provides very strong evidence in favour of the theory.

The Ideal Rubber

Thus far our attention has been focused on the individual molecule. We have yet to consider in more detail how the elastic properties of the molecule are to be conveyed to the material in bulk. When we consider this problem, we see that in order to be able to take up a variety of statistical forms in the way required by the theory, the molecular chains must have a freedom of movement comparable with that in a liquid. On the other hand, for the rubber to maintain a permanent shape, and to resist applied stresses, the molecules must somehow be fixed in their average positions relatively to one another. To meet these two rather contradictory requirements it is necessary to think of the molecules as linked together by a relatively small number of unbreakable bonds. These will be present in sufficient numbers to produce a complete, three-dimensional network throughout the material, but owing to the great length of the chains they need not seriously impede the freedom of motion of the segments of molecules between such points of junction.

We are thus led to postulate three necessary conditions for the occurrence of rubber-like elasticity, namely

- (1) The presence of long-chain molecules, with freely rotating links
- (2) Weak secondary forces around these molecules
- (3) A few points of cross-linkage, resulting in a loose 3-dimensional network

The ideal rubber may be thought of as a permanent network of long-chain molecules held together by unbreakable bonds, but otherwise completely free to move. The stress-strain properties of such an ideal network have been worked out by a number of authors. The most satisfactory development in this direction is due to Wall (1942), who obtained the following equations for the case of a simple elongation (or uni-directional compression) and simple shear respectively.

For elongation,

$$F_a = NkT \left(\alpha - \frac{1}{\alpha^2} \right),$$

where F_a is stretching force, referred to original section of 1 cm²; N is number of 'molecules', a 'molecule' being the length of chain between its points of junction to the network, k is Boltzmann's constant, T is absolute temperature, and α is the ratio of stretched to unstretched length.

For simple shear,

$$F_s = NkT\sigma,$$

where F_s is shear stress and σ is amount of shear.

There are a number of particularly interesting features of these equations. First, the stress-strain curve for elongation is non-linear, that is, Hooke's Law does not apply, while for shear the relation is linear. Secondly, the only molecular property which enters into these equations is N , the number of chain elements in the network. This quantity is simply related to the 'molecular weight' of the chain. The precise constitution of the molecule or the number of freely rotating links which it contains is of no significance in this connexion. The third point, which is related to this, is that one physical constant only is sufficient to define the elastic properties of a highly elastic material.

I have extended the elastic network theory to the case of a deformation of any type, and shown experi-

Fig 4 DOUBLE REFRACTION IN RAW RUBBER. EACH POINT REFERS TO A FRESH PIECE OF SHEET HELD AT THE APPROPRIATE EXTENSION FOR ONE HOUR.

mentally that the resultant equations give a reasonably satisfactory account of the properties of well-vulcanized rubber under a number of different types of deformation, except under very high strains, when the underlying assumptions of the theory are no longer applicable

Application to Real Materials

Having now defined the conditions under which rubber-like behaviour is to be expected, let us inquire to what extent real materials satisfy these conditions, and the way in which the non-fulfilment of these conditions leads to departures from the simple behaviour of the ideal rubber

The first point of difference is that in practice rubber-like properties appear only within a certain range of temperature. At low temperatures rubbers are transformed to a glass-hard condition. Below the transition temperature the molecular chains become immobile, the thermal energy no longer being sufficient to overcome the secondary forces between the molecules. For a material like natural rubber, these secondary forces are relatively weak, and the transition temperature is very low (-70°C). If the intermolecular forces are comparatively strong, the transition temperature is very much higher. This is exemplified by polymethylmethacrylate (Fig 1), which is a glass at normal temperatures (being extensively used for its non-splintering property), but becomes highly elastic above about 70°C .

Rubber-like properties may also be lost at high temperatures, where, in the case of polymers which are not cross-linked, the molecules become sufficiently mobile to slide bodily past one another, the rubber thus becoming a viscous liquid. The longer the molecules, the higher the temperature at which this effect becomes noticeable.

This plastic property of rubber and the 'thermo-plastics' is made use of in the processes of moulding, extrusion, etc. In the case of rubber the final form is 'fixed' by vulcanization—that is, combination with sulphur—which leads to a chemical cross-linking of the molecules.

Crystallization

So far I have omitted one very important phenomenon which profoundly affects the mechanical behaviour of rubber, namely, crystallization. If raw rubber is held at temperatures below 0°C for several days, it becomes comparatively hard and inelastic, and at the same time loses its transparency. This state is not to be confused with the glassy state, which occurs on quickly cooling to very much lower temperatures. The X-ray diffraction pattern of normal 'amorphous' rubber is like that of a liquid, there being only a single broad halo present. The same pattern is given in the glass-hard state. But the slowly frozen rubber shows a number of well-defined rings, which are to be interpreted as due to the presence of crystallites oriented at random, as in a powder.

Owing to the enormous length of the molecules, there are significant differences between the process of crystallization in rubber and in an ordinary low-molecular liquid. The crystallites are separated by regions of 'amorphous' or disordered molecules (crystallization is never complete), and, furthermore, a single molecule may pass alternately through several crystalline and amorphous regions. Thus the crystallites are bound together by amorphous rubber. This

Fig 5 POSSIBLE CHAIN FORMS FOR SYNTHETIC RUBBER GR-S (BUTADIENE-STYRENE POLYMER)

intimate binding of amorphous and crystalline components leads to a certain indefiniteness in the melting point of the crystalline phase, but at the same time imparts a degree of flexibility or toughness which is normally absent from crystalline bodies. The peculiar advantages of this type of molecular structure are made use of in polyethylene, which is chemically the same as paraffin wax, but has a much higher molecular weight. It is flexible, yet sufficiently hard for use as a cable-insulating material, and since the crystals hold the structure together vulcanization is unnecessary. The exceptionally valuable dielectric properties of the pure hydrocarbon are thus unimpaired.

Crystallization occurs not only in unstretched rubber at low temperatures, but also in stretched rubber at ordinary temperatures. By stretching, the molecules are brought into an approximately parallel arrangement, which greatly facilitates the crystallization process.

In stretched crystalline rubber the crystals all have one axis pointing in a fixed direction. Viewed by X-rays, this kind of arrangement gives rise to a series of spots arranged in a characteristic pattern. This pattern bears a rather strong resemblance to the X-ray pattern of natural fibres (cotton, wool, etc.), and in fact, stretched crystalline rubber behaves mechanically like a fibrous material, as Hock showed in 1924. If stretched crystalline rubber is frozen in liquid air and hammered, it splits along the fibre axis, just like a piece of wood. Also, it is very easily torn along the direction of the grain, but is, of course, exceedingly tough in other directions.

The rubber crystal is birefringent, hence stretched rubber is highly doubly refracting. If a piece of vulcanized rubber is stretched between crossed 'Polaroid' plates, a succession of brilliant interference colours is developed as the extension increases, on retraction, the effect disappears. If the same is done with unvulcanized rubber, the effect does not disappear entirely on removal of the tension, in this case the crystals are more permanent. The

method may be employed for the quantitative study of crystallization in stretched rubber. Fig 4 shows the birefringence of raw rubber as a function of the elongation

The Synthetic Rubber GR-S

Before concluding, I should like to devote a few words to the consideration of the general purpose synthetic rubber GR-S now being produced in considerable quantities. This rubber, like the German 'Buna', is formed by polymerizing together butadiene and styrene. The chains are thus lacking in regularity (Fig 5), since these two components occur in a random order, with the result that crystallization is not possible. This probably accounts for the much lower tensile strength of GR-S vulcanizates which do not contain a reinforcing agent like carbon black, compared with similar natural rubber vulcanizates. Moreover, there would appear to be a possibility of the formation of branched chains (Fig 5b) leading to a cross-linked structure. It is suggested that this effect may account not only for the comparative difficulty encountered in milling it to a suitable softness, but also for its most unfortunate lack of self-adhesion. Self-adhesion involves a mutual diffusion at the surface of contact, any branching or cross-linking of the chains will considerably reduce such diffusion.

DIAGNOSIS OF MINERAL DEFICIENCIES IN CROP PLANTS*

By PROF T WALLACE

Long Ashton Research Station, Bristol

LIEBIG, in enunciating his mineral theory of the nutrition of crops in 1840, advanced the view that simple plant analysis would suffice to provide the data to determine the mineral requirements of crop plants and the amounts of mineral nutrients necessary to add to the soil to make good shortages due to removals by crops.

The field experiments of Lawes and Gilbert soon showed this conception to be erroneous and resulted in attention being focused on field trials and soil analysis as means of solving problems of crop nutrition, including deficiencies of mineral elements. From that time until 1920, these remained practically the only two methods in general use for determining deficiencies of mineral nutrients and the fertilizer needs of crops, and they still continue to play important parts in the solution of these problems.

Since 1920, however, other methods for diagnosing the mineral status of crop plants have been developed, based primarily on the plants themselves. In attacking problems in the field these methods are given complementary roles, and field trials and soil analysis are also included, with the result that problems are attacked from many angles and a choice of methods is available to suit the varied conditions which occur.

The new methods include visual diagnosis, foliage spraying, injection of leaves and stems, and chemical analysis of leaf laminae and petioles and of stems.

In practice it has been found that none of the methods used alone will provide a complete solution of deficiency problems in all circumstances, but when

used in complementary roles and with varied emphasis to suit different conditions, they have proved effective in solving very diverse and difficult problems.

Visual Symptoms of Mineral Deficiencies*

The visual symptoms which result from mineral deficiencies in crop plants have proved a valuable aid in diagnosis and form the basis of the visual method discussed later. In view of the importance of this method to technical agriculturists, it was considered worth while to devote one lecture entirely to the subject of deficiency symptoms.

Although the symptoms produced are very varied they allow of some classification and grouping. The deficiencies of nitrogen, phosphorus, potassium and magnesium always affect older tissues first, and the visual signs progress systematically from the older to the younger parts of the plants, whereas the deficiency effects of calcium, iron and boron invariably appear first in meristematic tissues and often result in the death of growing points.

In field crops in Great Britain, deficiencies of all the essential elements, with the exception of sulphur, copper, zinc and molybdenum, have been recorded and frequently occur, and it is thus of interest to summarize some of the main features of the deficiency effects which have been observed.

The effects produced by nitrogen deficiency are very consistent over a wide range of plants. Growth is greatly reduced, stems are upright and thin, and lateral shoots are few, leaves are small and usually pale green in colour, flowering and fruiting are much reduced, and autumn tints of leaves, stems and fruit are usually brilliant, consisting of yellow, orange, red and purple colours. Defoliation is premature.

Phosphorus deficiency produces many effects similar to those resulting from nitrogen deficiency but leaf symptoms are more variable. They may take the form of high colorations as for nitrogen deficiency but more often the tints are dull shades of purple, or tints may be absent altogether, the leaves remain a dull, lustreless, olive green, or the margins may become 'scorched'.

Potassium-deficient plants are generally squat in habit because of short stem internodes and, unlike deficiencies of nitrogen and phosphorus, lateral shoot may be abundant while shoots may die back. Marginal leaf scorch is a very common symptom, but leaves may also show tip scorch, chlorosis, spotting and backward or forward curling of the lamina. Bright tints are often lacking, though not invariably so.

Calcium deficiency results in the death of the growing points of shoots, which condition may lead to the development of adventitious laterals, and to the distortion, wilting and scorching of leaf margin, collapse of petioles and the death of flowers. Root growth is much restricted and tuber formation seriously affected.

Magnesium deficiency is remarkable for the diversity of leaf effects produced. These include chlorosis, brilliant tinting with well-defined colour pattern, interveinal necrosis (both central and marginal) and spotting. The effects produced are often highly spectacular and ornamental. Defoliation is generally serious and may follow very quickly after the appearance of leaf symptoms. Deficiency effects usually develop at a relatively late stage of growth.

* Summary of two lectures delivered at the Royal Institution on January 30 and February 6.

* For a full account and for illustrations of visual symptoms, see 'The Diagnosis of Mineral Deficiencies in Plants by Visual Symptoms' (with 1944 Supplement) by T. Wallace (H.M. Stationery Office) 15s.

Iron deficiency is characterized by chlorosis of the foliage, which develops first on the young leaves at the tips of shoots and later spreads to the older foliage. As the veins often remain green the chlorotic pattern may take several forms, such as mottling or striping, according to the venation of the leaf.

The effects of manganese deficiency vary considerably. Many plants show leaf chlorosis similar to iron deficiency, but others, like oats and peas, develop symptoms unlike those produced by any other deficiency. Thus oats show lesions of the leaf tissues—grey speck—and peas lesions in the flat surfaces of the cotyledons—marsh spot.

Boron deficiency effects are notable both for their diversity and severity. They result from abnormalities in the development of meristematic tissues. The effects for individual crops are often so striking that many have been given descriptive names by growers, for example, heart rot of sugar beet, brown curd and hollow stem of cauliflower, cracked stem of celery and brown heart of swede. The injuries produced may affect growing points, epidermis, vascular tissues or pith.

Visual Diagnosis

In its simplest form, visual diagnosis consists of a comparison of plants growing under conditions of mineral deficiencies with suitable standards of deficient plants, usually in the form of photographic records and detailed descriptions. In practice, wherever possible, use is made of 'indicator' plants. These are plants which show characteristic effects for particular deficiencies and on which the deficiency symptoms are readily recognized. Examples of such plants are oats as an indicator plant for manganese deficiency, sugar beet for boron and potato for potassium.

Where indicator plants are present in instances of deficiencies in the field, particular deficiencies can usually be identified by mere inspection of the visual symptoms, but where this is not possible other methods must be used either wholly or in a confirmatory role.

Where the cropping potentiality of land is unknown, as has frequently occurred in the breaking up of new areas for arable cropping during the War, the visual method may be employed on special indicator plots. These plots combine indicator plants as crops sown in strips, crossed with a number of manurial dressings, which arrangement results in all the crops growing under conditions of the presence and absence of each of the particular elements likely to be deficient. This scheme has proved effective in solving a number of difficult problems.

The visual method cannot be applied in instances where symptoms are masked or prevented from developing by attacks of certain insect pests and fungus diseases and by certain other factors.

In applying the method, it is often useful to make observations on certain soil characters, for example, pH, texture and drainage, and in all doubtful diagnoses confirmation must be sought in the complementary methods.

Foliage Spraying and Plant Injection

These two methods both aim at introducing mineral nutrients into plants through stems and leaves, and they may be used as alternative procedures according to convenience of application.

Plants under experimental conditions may be supplied with their entire requirements of mineral

nutrients, either major or trace elements, by means of foliage sprays, and in practice spraying is often more effective than soil applications for supplying trace elements, particularly for manganese and iron, which often cannot be given through the soil where deficiencies of these occur. Spraying methods are very simple. It is only necessary to know the correct strength of spray to use and the best time to spray. A watering can fitted with a rose is suitable for use on all ground crops, while for trees a pressure sprayer is required.

¹ In practice, for trace elements the solutions used contain 1–2 oz. trace element compound per 5 gallon applied to 30 sq. yd. and for trees 3 lb. per 100 gallon is a suitable concentration, major elements are usually only applied to ground crops, at strengths of 1–2 lb. per 5 gallon. Where the foliage is difficult to wet it may be necessary to add a wetting agent.

Spraying is especially valuable for use with the visual method. Results are generally evident 5–10 days after treatment.

Both solids and solutions are used for injections, the former being useful only where woody stems are available for treatment. Solid injections are especially valuable for iron deficiency, as applications of iron salts to the soil are usually ineffective and sprays often damage the foliage. The technique of solid injections is based on the method originally evolved by Bennett¹.

Roach, at East Malling, has been responsible for the methods of liquid injection in use. The injections are made on laminae and petioles of leaves and on stems, and methods have been developed for use on plants as widely different as cereals and trees². The periods required for responses from liquid injections are similar to those for sprays.

With injection methods the time and dosage factors are again important.

Chemical Methods

In applying methods of chemical analysis to plants as a diagnostic procedure due regard is paid to established principles of plant physiology. The plant parts used comprise leaf laminae, petioles and stems, as representing parts of the plants which reflect most accurately their mineral status. It is usual either to compare the status of mineral nutrients of healthy and unhealthy plants growing in close proximity or to make comparisons with standards fixed from previous experience. In this latter connexion it has been found possible, when sampling methods are standardized, to fix 'threshold' values for the various elements in particular plants below which deficiencies may be expected. The chemical data are generally computed on a basis of dry matter.

In selecting material for analysis, samples must be comparable from the physiological point of view, otherwise growth and seasonal cycles may render comparisons invalid.

During recent years, methods for carrying out rapid chemical tests on plant tissues, suitable for use either in the field or laboratory, have been introduced³, which have proved useful in indicating deficiencies and in confirming the results of other methods.

The development of spectrographic and polarographic methods has also speeded up routine analytical procedures and made possible the detection of unusual elements giving rise to new problems.

A special technique for chemical diagnosis has been developed by Lagatu and Maume⁴ in France and by

Thomas and Mack⁵ in the United States, which has been designated 'foliar diagnosis'. The method compares the nutrient status of test plants with that of healthy, heavy-cropping plants, regard being paid to seasonal cycles of nutrients and to quantitative and qualitative aspects. The 'method' is, of necessity, somewhat slow for general advisory purposes.

Chemical methods, however, are not infallible and if used alone may fail to provide the correct solution to certain problems. This is particularly so in instances of iron deficiency, where the element apparently becomes immobilized within the plant tissues from a variety of causes, as in lime-induced chlorosis, some instances of potassium deficiency and in the presence of toxic concentrations of other elements.

Soil Analysis and Field Trials

During the course of long usage, these methods have undergone considerable elaboration, soil analysis chiefly by the development of methods of determining 'available' nutrients⁶ and by the introduction of rapid methods⁷, and field trials by the development of designs allowing of statistical analysis⁸.

The data provided by soil analyses can be of great value when used by an expert and supported by previous field experience, but they must be regarded only as pointers to probable mineral deficiencies since the intake of minerals by plants is not determined solely by chemical supplies in the soil. The method is chiefly of use for phosphorus and potassium deficiencies, and in providing data relating to acidity and organic matter.

As the response of the crop to a nutrient element, however the response may be obtained, must always be regarded as a final test of a deficiency of a particular element, field trials must always be of importance in diagnosis. But even here erroneous conclusions may be drawn, particularly so where trace element deficiencies may be remedied by changes in the pH of the soil. Thus, applications of sulphur to the soil may remedy a deficiency of manganese and alleviate deficiencies of iron and boron by lowering the pH, and conversely the application of lime may cure a deficiency of molybdenum. Moreover, soil dressings of manganese and iron salts are ineffective in many soils against these deficiencies, which nevertheless may be quickly and completely remedied by spraying or injection treatments.

The usual field trial methods may also be too slow in producing results for advisory purposes, as for example, for deficiencies of potassium and magnesium of fruit trees.

Experience with mineral deficiencies of crops in the field has shown that the problems may be very complicated and that no one method can be relied upon to provide a general solution. The most effective procedure is to use all available methods of attack in a complementary way, and in doing so, full use should be made of all the data which the plants themselves provide.

OBITUARIES

Sir Hanns Vischer, C.M.G., C.B.E.

THE death on February 19 of Hanns Vischer has removed a notable and commanding figure from the sphere of African interests. Even his entry, more than forty years ago, into the political service of Northern Nigeria was in itself a notable event, for by birth he was a foreigner and his previous contact with Africa had been in the mission field, neither of which circumstances could in those early days be regarded as an 'open sesame' to the British Colonial Service. But there was that in Vischer's make-up before which all prejudice, British or African, melted like snow in the midday sun, and the reason was not far to seek. The Hausa people, quick at all times to detect the idiosyncrasies of their alien overlords, proclaimed the secret of his influence in two words. Throughout the country he was known as Dan Hausa ('Son of Hausa')—perhaps the most significant nickname ever conferred on a European in West Africa. It meant that in him the Hausas recognized, not only a man who possessed an extraordinary command of their delightful and expressive language, but also one whose affection for them was equalled by his insight into the innermost recesses of the African soul. It meant that they had, as it were, adopted him. One had only to watch him in his daily avocations in those early days to realize how completely at home he was with every class of society—whether he was engaged in grave deliberations with emirs, viziers and other high personages of the ruling hierarchy, or whether he was chaffing the hucksters at the market stalls as he rode through Kano city. No less revealing was it to see him in his own home pick up a native drum and, squatting on the floor, croon local Hausa songs to his own accompaniment. So imitatively did he do it that, if he had been hidden behind a screen, one would have said that an African musician had been engaged to entertain his guests.

No one who knew Kano in the years before the War of 1914-18 will ever forget the spirit of the motley community over which Hanns and Isabelle Vischer presided at the headquarters of the Education Department at Nassarawa. Isabelle's influence was second only to her husband's. If Hanns had it all his own way with the men, it was to Isabelle that the women laid bare their joys, their absurdities and their sorrows. She was the true *uwargida*, the mother as Hanns was the father, of the great family.

It need scarcely be said how firmly Hanns and his wife were established in the affections of their British colleagues. Those—and they are now a much diminished band—who enjoyed their hospitality at Nassarawa before the War of 1914-18 will long remember the charm and gaiety of evenings spent in their company. Indeed, as one looks back, they, more than any two other people, seemed to embody the spirit that pervaded the Northern Nigeria Service in those early days—the light-heartedness, the good fellowship, the sport and, above all, the eager and adventurous interest in the problems of a fascinating and newly opened country.

Lack of space forbids me to speak of Hanns Vischer's later career, of his military service in the War of 1914-18 and of the widespread influence which he exercised as secretary of the Advisory Committee on Education at the Colonial Office and as secretary general of the International Institute of African Languages and Cultures. In these larger spheres his

great achievements have been widely known and acclaimed. If I have dwelt on the remote and less well-known period of his life in Northern Nigeria, it is because at that time the foundations of his future influence were laid—an influence which sprang from his passionate devotion to the people of Africa and the reciprocal devotion to him of the Africans whom he served so well. G J F TOMLINSON

Mr. Thomas Sheppard

WITH the passing of Mr. Thomas Sheppard at his home in Hull on February 18, the city has lost a notable character. Though officially the director of the Hull Museums for forty years (until his retirement in 1941), his activities ranged over a wide field, from organizing exhibitions directing attention to Hull's trade and commerce, and lecturing up and down the country on a variety of subjects, to contributing numerous articles to the Press.

As showing his diversity of interests, Sheppard was a past president of the Museums Association, the Yorkshire Geological Society, Hull Scientific and Field Naturalists' Club, Hull Geological Society, Hull Literary Club, Yorkshire Numismatic Society, Hull Publicity Club, Hull Luncheon Club, and the Hull Playgoers' Society, and a past chairman of the Conference of Delegates of Corresponding Societies of the British Association. He was also a member of the Hull University College Historical Committee, Hull Development Committee, and the Yorkshire Roman Antiquities Committee, and was local secretary when the British Association visited Hull in 1922. He issued two hundred Publications of the Hull Museums, edited the *Naturalist* for thirty years and was also responsible for the bibliographies of Yorkshire geology, and Mortimer's "Forty Years Researches".

Perhaps Sheppard's most important work was in connexion with geology, and he received the Lyell Award of the Geological Society of London for his contributions to this subject. In recognition of his scientific work, he received the honorary degree of master of science from the University of Leeds and he was made an associate of the Linnean Society.

During his long service as director of the museums of Hull, the Albion Street Museum, Wilberforce

House, the Natural History Museum, Museum of Fisheries and Shipping, the Museum of Commerce and Transport, Mortimer Museum of Prehistoric Archaeology, and the Railway Museum at Paragon Station were opened. In fact, he gained a well-known reputation of having very few scruples when it came to obtaining exhibits for his beloved museums.

A man of genial personality and a great sense of humour, he had been in failing health for some years, and the fact that his work was done, and the results of so many years of interest destroyed during the air raids on the city of Hull, contributed greatly to his death at the age of sixty-eight. J B FAX

Dr. E. C. Wiersma

ACCORDING to a brief announcement in *Die Chemist* of October 28, 1944, Dr. E. C. Wiersma died at Delft at the age of forty-two. He was known for his work at the Kamerlingh Onnes Low Temperature Research Laboratories at Leyden. Both independently and in collaboration with Dr. W. J. de Haas, Wiersma had published a number of papers on the influence of low temperatures on the paramagnetism of certain metals and salts. He studied the adiabatic cooling of magnetic bodies and the production of low temperatures by adiabatic demagnetization. In 1931 he published a classification of para-magnetic atoms, molecules and ions based upon their fields at low temperatures. He also deduced a thermodynamic scale for temperatures below 1° Abs.

WE regret to announce the following deaths.

Sir James Barrett, K.B.E., C.M.G., sometime vice-chancellor and later chancellor of the University of Melbourne, and a founder and original fellow of the Royal Australian College of Surgeons, aged eighty-three.

Engineer Vice-Admiral Sir George Goodwin, K.C.B., formerly engineer-in-chief of the Fleet and a past-president of the Institute of Metals and of the Institute of Marine Engineers, on April 2, aged eighty-two.

Dr. G. L. Taylor, of the Galton Laboratory Serum Unit, recently seconded to the Medical Research Council, aged forty-seven.

NEWS and VIEWS

Bessemer Gold Medal: Award to Mr. Harold Wright

MR. HAROLD WRIGHT, chief metallurgist to Dorman Long and Co., Ltd., Middlesbrough, has been awarded the Bessemer Gold Medal by the Iron and Steel Institute in recognition of his "valuable contributions made over many years to improve the technique of iron and steel manufacture". The Medal, which is the highest award conferred by the Institute, will be presented to Mr. Wright by the president, Mr. Arthur Dorman, at the annual meeting of the Iron and Steel Institute in London on May 9. Mr. Harold Wright has been a member of the Institute since 1902 and has served on its Council; he is a past president of the Cleveland Scientific and Technical Institution and of the Cleveland Institution of Engineers. He started work at the North Eastern Steel Works. While with Sir Bernard Samuelson, Mr. Wright took an

active part in the supply of molten basic iron to Dorman Long's Britannia Works when the latter firm introduced the hot metal process forty years ago. While in charge of the Newport coke ovens, Mr. Wright promoted the use of coke oven gas for town purposes. He first made the suggestion in 1902, but it was 1913 when the supply was first established. Mr. Harold Wright also possesses considerable geological knowledge, and has done a great deal of exploration work in connexion with the Cleveland ironstone deposits. He was also responsible for the introduction into local blast furnace practice of the use of rich foreign ores in the Cleveland burden. Mr. Harold Wright was appointed chief metallurgist to Dorman Long and Co., Ltd., in 1918. Last December the Company inaugurated a triennial Harold Wright Lecture to be given before the Cleveland Scientific and Technical Institution in recognition of his long and valuable service.

Dr. F. C. Steward

DR F C STEWARD, reader in plant physiology in Birkbeck College, University of London, has recently left for the United States to take up a temporary appointment as research associate in the University of Chicago, where he is to develop certain aspects of plant physiology and biochemistry in which Prof E J Kraus and the Chicago Department of Botany are interested. Dr Steward has been given leave of absence by Birkbeck College for this purpose, and the appointment is a sequel to the destruction in an air raid of the research laboratory in plant physiology at Birkbeck, which had been largely equipped by the Rockefeller Foundation. Dr Steward has been engaged since 1941 with the Ministry of Aircraft Production, where he developed a department dealing with statistics concerning the determination and forecasting of Royal Air Force requirements. It seemed that his return to botanical research would be delayed indefinitely by the destruction of his laboratory, so that the offer of Prof Kraus has rendered a real service to botanical inquiry.

Mrs. Neville-Rolfe, O.B.E.

MRS NEVILLE-ROLFE has resigned her office as honorary secretary of the British Social Hygiene Council. Fortunately this does not mean a severance of her interest in the Council. She has been elected a vice-president, and has also accepted a new office of honorary adviser, which will enable her to place at its disposal her great store of accumulated knowledge and experience. As honorary secretary of the National Council for Combating Venereal Disease from its foundation thirty years ago, she took the principal part in organizing the whole scheme of popular education in this subject—one hitherto taboo. In these early days the work of popular enlightenment on venereal disease was financed by a direct grant from the Exchequer, but the difficulty lay in persuading local authorities to avail themselves of the educational material offered by the Council, and in overcoming the resistance of many hospital authorities to the establishment of free clinics. In this work, and also in the organization of lectures to the armed forces during the War of 1914-18, Mrs Neville-Rolfe was indefatigable.

As the years passed, it became increasingly obvious that the problem of venereal disease was only one aspect of a larger one, that of social hygiene in its wide sense, and that the Council's work should cover this wider field so as to combat the causes leading to sexual misconduct—the absence of biological teaching of the adolescent, the lack of training of teachers and instruction of parents, and the need for amelioration of various relevant social malconditions. At the same time, the name was changed to British Social Hygiene Council, and Mrs Neville-Rolfe organized the wider field with undiminished zeal. In addition, however, to this work on the home front, she was able to extend its scope to the Dominions and the Colonies, in many of which branches and colleague organizations were established. Through the collaboration of the Government Departments concerned, several overseas visits and commissions were arranged and carried out by the Council between the years 1920 and 1936. Mrs Neville-Rolfe, in 1926, spent six months in India, touring many provinces and States on the invitation of their respective Governments. She also, at various times, visited Canada, the Far East, Palestine, Cyprus, Jamaica

and Southern Rhodesia, investigating local conditions and organizing measures for reducing the incidence of venereal disease. Liaison was also established internationally with the various foreign societies working in this field, and she was one of the founders of the Union Internationale Contre le Pêril Vénérien, holding office as vice-president, and chairman of its Ports Commission. In 1941, she was awarded the Snow Gold Medal of the American Social Hygiene Council for work in social hygiene (*Nature*, 147, 261, 1941).

Chemical Technology at Imperial College

THE Imperial College of Science and Technology, with the approval of the Court of the University of London, has lately accepted from Messrs Courtaulds, Ltd, a benefaction intended to promote its work in the field of chemical technology. This benefaction, which is calculated to yield an income of £3,000 per annum in perpetuity, will be administered for the present by a small body of trustees, and will permit the institution in Imperial College of a Courtaulds chair of chemical engineering, to which it is expected that an appointment will be made this year. It will also provide for other needs in the Department of Chemical Technology, in ways that will be decided by the trustees after consultation with the College. The Governing Body of Imperial College has recorded their most grateful appreciation of the gift, which is an outstanding event of this centenary year.

Visits of French and Belgian Medical and Scientific Workers

A FRENCH medical delegation of ten is visiting Great Britain during April 7-17 as guests of the British Council, in conjunction with the Royal College of Physicians, and will be entertained by other organizations, including the Royal Society of Medicine. The delegation will see hospitals in London and elsewhere and visit Oxford and Cambridge. The members are Académie de Médecine Prof Baudouin, dean of the Faculty of Medicine, Paris, Prof A Lemierre and Dr P F Armand-Delille, Conseil Supérieur de Médecine. Dr Ravina, Dr A Laporte and Dr H Descomps, Provinces. Prof C Soula (Toulouse), Prof Gernez-Rieux (Lille), Prof Roche (Marseilles) and Dr Nedelec (Angers). The first of four groups of representatives from Belgian universities, whose visits are being arranged by the Belgian Fondation Universitaire, will be in Britain during April 16-30. The other groups will follow at intervals between May and July. The members of the first group are Prof V Bohet, professor of English, Liège, Prof N Goormachtigh, Faculty of Medicine, Ghent, Prof P Govaerts, Faculty of Medicine, Brussels, Prof M F L Hemptinne, Faculty of Science, Louvain, Prof C J Jungers, Faculty of Science, Louvain.

Bibliography of the British Flora

WITH the view of eventual publication, it is proposed to compile a bibliography of the British Flora. One section of this, on local botany, would comprise all publications, which it is possible to trace, dealing wholly or partly with the flora of any area within the British Isles. This section would include local floras and works on topographical botany, and all publications, such as local and county histories, guide books, periodicals and newspapers, etc, in which plant lists of particular areas have appeared, manu-

scripts of 'sufficient importance and authenticity would also be listed. Where, however, only incidental mention is made of plant localities, as in many of the standard floras of Britain and in monographs, these would be omitted from this section.' The compilation will entail a large amount of research and will be possible only with the co-operation of helpers who have the requisite local knowledge of the literature of their areas. The editors are Mr J. S. L. Gilmour, Mr H. A. Hyde, Mr H. S. Marshall, Mr N. Douglas Simpson and Dr G. Taylor. Those willing to help in this compilation should communicate with Mr N. Douglas Simpson, Maesbury, 3 Cavendish Road, Bournemouth, Hants, indicating when they can begin work, in what areas they are interested and to what libraries and periodicals they have access.

Early Scottish Prehistory

It is doubtful whether it can be proved that any cultures earlier than the Mesolithic existed in Scotland. This is perhaps surprising, as there would seem to have been no climatic reason why Scotland should not have been habitable during the main interglacial epoch in the middle of the Great Ice Age in any event. Maybe the scanty populations of the Old Stone Age never reached the extreme north-western edge of the Old World. Mesolithic industries contemporary with those farther south have been unearthed at a number of sites. But many of the apparently Mesolithic industries in Scotland are actually much more recent in date and contemporary with the Neolithic or even early Metal Age farther south. Even in the Cleveland hills of Yorkshire, sites are known where pigmy tools of Mesolithic facies occur in real association with leaf-shaped arrowheads. Such an overlap of cultures is not surprising. The Neolithic civilization in Britain was rather due to the coming of new modes of life than to hordes of invaders, in large part it was a case of 'neolithizing' the autochthonous inhabitants. Off the beaten track, the older culture continued to survive, influenced to a greater or less degree by the more advanced ideas spreading slowly over the land.

Much of our information of these early cultures in Scotland is due to the work of A. D. Lacaille, who is collecting a corpus of material for eventual publication after the War. Recently, he gave a paper to the Society of Antiquaries of Scotland on the stone industries associated with the raised beach at Ballantrae. The sites are in Wigtownshire and south Ayrshire, and the specimens were collected on the tilled surface of the raised beach, which itself dates to the period of the Littorina Marine transgression. With the specimens of Mesolithic facies were found others, Neolithic in appearance. The evidence would seem to point to the introduction there of the Neolithic civilization towards the end of the Atlantic post-glacial phase. Among the Mesolithic types of implements occur specimens which recall some found in northern Irish sites. Thus tanged points resembling those from the valley of the River Bann have been found. Mr Lacaille's definitive publication will be awaited with interest. There is still a lot to be learnt about the cultural overlaps in Scotland and the various influences that went to form the earliest Stone Age cultures north of the Cheviots.

Archæological Expedition to Mexico

THE War has forced the National Geographic Society to curtail its scientific field expeditions, but the archæological studies that have been made

annually since 1937-38 in southern Mexico under the sponsorship of the Society and the Smithsonian Institution will continue. The seventh expedition, headed by Dr. Matthew W. Stirling, is on its way to the southernmost Mexican State of Chiapas where, digging into huge burial mounds and clearing dense jungle growth, he will continue to reveal some of the secrets of pre-Columbian civilization in this hemisphere. Dr. Stirling is accompanied by his wife, Marion Stirling, who is also an archæologist, and Richard H. Stewart, staff photographer of the National Geographic Society. The expedition this year plans to conduct its studies in the mountains east of the Isthmus of Tehuantepec.

Social Implications of Engineering

ON March 28, Sir Harry Railing, president of the Institution of Electrical Engineers, delivered an address to the London Students' Section of the Institution, taking as his subject the social implications of engineering. Sir Harry stressed that it is essential for the engineer to grasp the inner meaning of his work and the mission he has to fulfil in his everyday life. To do this, a full appreciation of past achievements is necessary, and he must feel that, however small or large his contribution, he is a vital unit in a powerful living force. Material progress has been so remarkable that too little attention has been paid to the development of the lives of human beings. Humanity should have been trained and encouraged to accommodate itself to the increased impetus of science and engineering, so as to avoid a disastrous piling up of pent-up energy. Engineers should have foreseen these consequences more clearly and made the world realize that increasing material knowledge necessitates the acceptance of new responsibilities both on the part of the individual, the community and the State.

Sir Harry Railing does not believe in early specialization. When specialization becomes necessary, engineers should retain a broad understanding of the work of others in as wide a field as possible. Of the relative value of the methods most useful in engineering work, mathematics and physics are of paramount importance. But engineering involves also the handling of human beings, and it vitally affects their lives. A broader understanding of sociological problems is necessary, and if the engineer's work neglects the spiritual aspect it is liable to be a dismal failure. For the well-being of the community the scientific approach should be applied to social problems and politics, but its limitation should be borne in mind. Man is finite, not infinite, and from this should spring humility and tolerance of others.

Jubilee of the *Astrophysical Journal*

WITH the current issue of the *Astrophysical Journal*, this periodical completes its hundredth volume. Founded in 1895 by Hale as an international review of spectroscopy and astronomical physics, the *Astrophysical Journal* soon became the acknowledged medium for the publication of research, and especially of observational research, by English-speaking astrophysicists. Although the original plan of appointing collaborating editors from countries other than the United States has been recently abandoned, the international character of the journal is still attested by its contents pages. During the past fifty years such famous names as those of Cornu, Huggins, Belopolsky, Kayser, Schuster, Newall and Alfred Fowler have appeared beside those of their American colleagues,

and such contemporary names as Adams, Millikan, Russell, Shapley and Otto Struve are likely to be as well remembered in the future. Nearly all the major spectroscopic and astrophysical advances of the past half-century are recorded in the first hundred volumes—the Fabry-Perot interferometer, the Rowland solar wave-length table, the first photographic trigonometrical parallaxes and spectroscopic parallaxes, the 100-in telescope, the Einstein and the nebular red-shifts, 'nebulum' and super-novæ, to mention only a few. With the completion of the 200-in telescope after the War, science may look to see its boundaries enlarged yet again in the pages of the *Astrophysical Journal*.

Temperature Compensation in Instruments

A PAPER read recently in London by Dr G F Tagg before the Institution of Electrical Engineers has for its theme the fact that one cause of errors in indicating and recording instruments is their use at a temperature other than that at which they were calibrated. Most of the physical properties of materials on which instrument performance depends vary to a greater or less degree with temperature. It is therefore necessary when designing an instrument to reduce to a minimum any errors caused by changes in temperature, and if possible to make them negligibly small. This is done either by adopting a design such that the temperature errors themselves are very small, or by introducing other changes with temperature which will compensate them. An account is given in the paper of the more common methods employed, each method being briefly discussed to indicate the best arrangement for each type of instrument. The instruments considered are ammeters, voltmeters, millivoltmeters, wattmeters and rectifier-operated and thermocouple instruments.

Recent Earthquakes

DURING the third quarter of 1944, fifty-eight earthquakes and tremors were recorded at Toledo, Spain, while during the same quarter twenty-six strong earthquakes were recorded at the Dominion Observatory, Wellington, New Zealand. The earthquake of October 29 was felt with Scale 5 (modified Mercalli) in the southern parts of North Island and Taumarunui, the shock of November 25 was felt at Karama with Scale 4 and that of December 24 was felt at Timaru with Scale 3 intensity. The United States Coast and Geodetic Survey determined the epicentres of several shocks which occurred during the quarter. On October 23 the epicentre was in Ecuador, South America, on December 7 (lat 33° N, long 137° E) off Japan, on December 10 in the New Hebrides Islands and on December 12 in the Aleutian Islands.

The Ray Society

At the annual general meeting of the Ray Society held on March 22, Mr A D Cotton, president of the Linnean Society, was elected a vice-president and Prof F Balfour-Browne, Dr W S Bristowe and Dr John Smart new members of Council. It was announced that Dr F E Zeuner's volume on "The Pleistocene Period" would soon be ready for distribution, and that Dr Dawes's work on "The Trematode Parasites of British Fishes" was nearly ready for printing. Owing to the increase in costs, Dr Zeuner's book will form the issue to subscribers for the two years 1942 and 1943, and it is intended that Dr Dawes's volume shall be issued for the year 1944.

Other works are in preparation, but no dates can yet be announced for their probable publication.

Oliver Lodge Scholarship

IN order to commemorate the silver jubilee of the Radio Section of the Institution of Electrical Engineers the Council of the Institution has founded a research scholarship which is to be called the Oliver Lodge Scholarship. It will have a basic annual value of £250 and will be tenable for one year, but may be extended for a second year. The Council wishes to encourage scholars to travel and, after approval of a candidate's programme, may make an additional grant for this purpose. The scholar will be required to carry out research in a subject closely allied to radio engineering. Further particulars and nomination forms can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2. The closing date for receiving nominations is May 15, 1945.

Announcements

THE following have been elected by the Governing Body to honorary fellowship of the Imperial College of Science and Technology: the Most Hon the Marquess of Crewe, Mr C S Garland, Mr Percy Good, Dr Andrew McCance, the Right Hon Lord Rayleigh, Prof J S Truscott, Lieut-General Sir Pierre Van Ryneveld, Prof W W Watts, Prof A N Whitehead and Dr H E Wimperis.

MR O S PUCKLE, recently of the Research Department of Messrs A C Cossor, Ltd, has been appointed chief engineer of R F Equipment, Ltd, Plantation Road, Amersham, Bucks, with a seat on the board. In particular he will be responsible for research and development.

THE posts of inspector-general of forests to the Government of India and president of the Forest Research Institute and Colleges have been separated. A separate post of president of the Forest Research Institute and Colleges, Dehra Dun, has been created, this post is being filled by Mr C E Simmons. The inspector-general of forests (Sir Herbert Howard), with his office and staff, has been transferred to New Delhi. His address in New Delhi will be "Inspector-General of Forests, Department of Education, Health and Lands, New Delhi", and his telegraphic address will be 'Igforest, New Delhi'. All correspondence connected with research and education at Dehra Dun should be addressed to the President, Forest Research Institute and Colleges.

TRINITY COLLEGE, Cambridge, has decided to resume in the present year the annual offer of a research studentship which has been suspended since 1941. The studentship is open to graduates of other universities who propose to go to Cambridge as candidates for the degree of Ph D, provided that on June 1, 1945, they have not commenced residence in the University of Cambridge and are not more than twenty-six years of age. In computing the age of a candidate for this purpose, any days of war service will be deducted from his actual age. Candidates should apply through the principal authority of their university, and applications should reach the Senior Tutor of Trinity College (from whom further particulars may be obtained) before June 1, 1945.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Adhesion of Lubricated Metals

It is evident, both from an examination of the contours of solid surfaces, and from measurements of the electrical conductivity between metals¹, that the real area of contact between two surfaces is only a small fraction of the apparent area of contact. This means that even with quite small loads very large pressures will be developed at the few points of real contact. It has been shown that these pressures are sufficient to cause local adhesion and welding of the surfaces at the points of contact, and that the tangential force required to shear the junctions is a major component of the friction between sliding metals².

The reality of this metallic welding may be demonstrated by a microscopic examination of sections of the track, and an example of this is given in Fig. 1. A curved copper slider was allowed to slide once (at low speed, 0.01 cm. per sec.) over a mild steel surface. The load was 4,000 gm. and the experiment was done both with clean and with lubricated surfaces. When the surfaces were clean, the coefficient of friction was high ($\mu = 0.6-0.7$) and many tiny particles of copper were left adhering to the steel. Fig. 1 is a photomicrograph of a taper section of one of these particles. It was made by protecting the steel surface with an electro-deposit and cutting a section at a very oblique angle so that the magnification of the vertical component of the surface contour was ten times that of the horizontal component. A modification of the technique described by Nelson³ was used. In this photograph the vertical magnification is 5,000 and the horizontal 500. It will be seen that the copper is welded firmly on to the steel, and the shearing of the copper has caused a plucking up of the steel above the general level of the surface. This would lead to a wearing away of the

FIG. 1. TAPER SECTION SHOWING COPPER FRAGMENT (DARK) WELDED ON TO STEEL SURFACE; NOTE PLUCKING UP OF STEEL. VERTICAL, $\times 5000$; HORIZONTAL, $\times 500$.

FIG. 2. CHEMICALLY DEVELOPED TRACK OF COPPER SLIDER ON A CLEAN (ABOVE) AND LUBRICATED (BELOW) FLAT STEEL SURFACE. THE TRACK LIES BETWEEN THE ARROWS, WHICH SHOW DIRECTION OF SLIDING. BLACK AREAS ARE COPPER. $\times 11$.

steel, and shows graphically how a hard metal can be worn by a soft one.

When the metals are lubricated, the friction falls to about $\mu = 0.15$. The earlier frictional and conductivity experiments have shown that metallic contact and adhesion still occur through the lubricant film, but they are, of course, greatly reduced and difficult to detect by the taper section method. The existence of this localized adhesion and its distribution over the surface of the track may, however, be revealed by a chemical technique using a method similar to that described by Hunter, Churchill and Mears⁴ for the detection of metallic inclusions. A gelatine-coated paper which has been immersed in a suitable electrolyte is placed on the surface of the metal to be examined and a current passed so that the foreign metal is electro-dissolved into the gelatine. If an appropriate reagent is present in the gelatine, very small quantities of metal may be detected. In this case dithio-oxamide was used to detect copper, and Fig. 2 shows the patterns obtained by allowing the copper slider to pass once over polished steel (a) when clean and (b) when lubricated with 1 per cent lauric acid in paraffin. The black areas indicate copper, and it will be seen that the adhesion of copper to the lubricated steel surface is quite considerable. The track of the slider is about 1 mm. wide, and adhesion has occurred at a number of small points distributed over it. There is a tendency for these points to lie on straight lines in the direction of sliding, and this probably corresponds to high spots on the copper slider.

Similar experiments of a more quantitative nature were carried out with copper on platinum, both clean and lubricated with solid potassium stearate. Any copper adhering to the flat platinum surface after the copper slider had passed over it once was removed electrolytically from an appropriate length of track and micro-estimations made with sodium diethyl dithiocarbamate. With the clean metals the friction was high and irregular ($\mu \sim 1.8$) and the surface density of copper adhering to the platinum was 2×10^{-5} gm. per mm.² of track. With lubricated metals the amount of copper adhering to the platinum was 1.7×10^{-7} gm./mm.². If this copper were spread evenly over the platinum in the path of the slider, it would correspond to a layer about fifty atoms thick; but as the photographs show, it is distributed

irregularly over the surface of the track in a number of small discrete particles of varying size.

In a recent interesting paper, Sackmann, Burwell and Irvine⁵ describe the application of a radioactive method to the measurement of the pick-up of metals. Their results are not directly comparable with ours since they measure the amount of metal which accumulates on the small curved surface of the slider after it has traversed a certain distance; but again the results confirm the observation that metallic adhesion occurs through the lubricant film.

Raman Spectrum of Quartz

SINCE quartz is transparent in the ultra-violet, the employment of the powerful technique for Raman-effect studies developed by Rasetti, in which the 2537 Å. radiation from a water-cooled magnet-controlled mercury arc is the exciter, naturally suggests itself for this crystal. Rasetti's own studies¹ included quartz, but his exposures were very short (20 min.) and it is therefore not surprising that he recorded only fourteen distinct frequency shifts as against the twenty shifts found earlier by Gross and Romanova² with the 4358 Å. radiation of the mercury arc as the exciter and exposures of the order of 120 hours. However, by prolonging the exposure with the Rasetti technique to 48 hours for a crystal 15 cm. long, I have recorded a very intense spectrum reproduced herewith, in which no fewer than forty-one distinct frequency shifts have been observed and measured. All the twenty-one newly observed frequency shifts are represented by relatively feeble lines and evidently belong to the Raman spectrum of the second order, namely, octaves and combinations of the fundamental frequencies of the quartz lattice. The accompanying table gives the measured frequency shifts in wave-numbers, the relative intensities of the lines being roughly indicated on an arbitrary scale within brackets.

Frequency shift and strength	Assignment	Frequency shift and strength	Assignment
127 (20)	E_1	859 (1)	
145 (2)		890 (1)	$B_2 + E_3$

ABOVE, RAMAN SPECTRUM OF QUARTZ. BELOW, COMPARISON SPECTRUM OF MERCURY ARC.

According to Bishambar Dayal Saksena³, the group of three silicon and six oxygen atoms present in the unit hexagonal cell of the quartz lattice has sixteen distinct fundamental modes of vibration, four of the A class active only in Raman effect, four of the B class active only in infra-red and eight of the E class active in both. The fundamentals shown as such in the table are distinguished by their relatively large intensities, and those of the A class by the strong polarization of the lines. The four fundamental frequencies coming under the B class have been assumed from the infra-red measurements of Plyler⁴ as $B_1 = 385$, $B_2 = 488$, $B_3 = 800$ and $B_4 = 1,190$ wave-numbers. The identifications of some of the weaker lines as overtones and allowed combinations are shown in the table, but are only provisional.

Absorption Spectra of Mercury Halides

RAO¹ has recently observed the absorption spectra obtained when halides of mercury were placed in a heated steel tube. New systems attributed to HgCl and HgBr were found and analysed, leading to values for the dissociation energies of these molecules. Comparison of the wave-lengths of these 'new' bands with tables² of collected band heads of known molecules reveals coincidences with CuCl and CuBr. More detailed comparison shows that Rao's Q_1 heads of 'HgCl' coincide with the D system of CuCl, and the Q_2 heads with the E system. For 'HgBr' all the assigned band heads can be identified with the B system of CuBr; other unassigned bands of 'HgBr' coincide with bands of the A system of CuBr. The identity is quite convincing.

In Rao's experiments the copper probably came from the steel tube. I have observed³ CuCl bands in the spectrum of a flame burning in a steel tube. The identification of the emitting molecule of a new band system is not easy, but it is not always realized that impurities as frequently cause trouble in absorption as in emission. It seems desirable to point out incorrect assignments of this type to save later investigators wasting time, and possibly using incorrect data for theoretical work.

Inverse Statistical Variates

HALDANE¹ has recently explained a method of using a haemocytometer in which counting is stopped when a fixed number of cells has been recorded. This sampling technique, with suitable modifications, can be applied to other populations and the theory reveals some interesting relationships.

In ordinary binomial sampling, if the variate (r) is the number of occurrences of a certain event when it is given a fixed number (N) of opportunities of occurring, in each of which the probability of occurrence is π , then the seminvariant-generating function of r is

$$L_N(t) \equiv \sum_{r=0}^N \ln \sum_{r=0}^N \pi^r (1-\pi)^{N-r} C_r^N \\ = N \ln (1-\pi + \pi e^t) = NL_1(t).$$

If, however, the number of occurrences is fixed (R), the probability that n opportunities will be required is equal to the probability that the event will occur $R-1$ times in the first $n-1$, compounded with the probability of an occurrence at the n th opportunity. Hence it is

$$\frac{(n-1)!}{(R-1)!(n-R)!} \pi^R (1-\pi)^{n-R},$$

(the coefficients being those of the expansion of a binomial of power $-R$), and the seminvariant-generating

function of n can be shown to be $-R \ln \left(1 - \frac{1-e^t}{\pi}\right)$.

This seminvariant-generating function is simply $RL_1^{-1}(t)$, where $L_1(L_1^{-1}(t)) \equiv t$ —a rather striking result. Moreover, the coefficients of variation of r and n are equal when $R = N\pi$. In this case, the value of R in the distribution of n is the mean value of r , while the value of N in the distribution of r is the mean value of n . In view of these relationships between the two distributions, I suggest that the sampling with a fixed number of occurrences should be termed *inverse binomial sampling*.

The Poisson limit is obtained on writing $\pi = k\mu$, $x = nk$, $X = Nk$, and then making k vanish while x , X and μ remain finite. The seminvariant-generating functions of r and x become $X\mu(e^t - 1)$ and $-R \ln(1 + t/\mu)$, which are of the form $Xf(t)$, $Rf^{-1}(t)$, where $f(f^{-1}(t)) \equiv t$; and the coefficients of variation are equal when $R = X\mu$. The first of these seminvariant-generating functions is that of the usual Poisson limit, while the second corresponds to a distribution of Pearson's Class III, in which the variate can take any non-negative value, and such a distribution could therefore be termed the *inverse* of the Poisson distribution. That inverse Poisson sampling with $R = 1$ gives a Class III distribution of this type has already been shown by Marsden and Barratt².

A similar relation appears in the theory of the effect of Brownian motion on the times taken by colloid particles to travel a fixed distance under electrophoresis or convection. The general theory, developed by using the properties of seminvariant-generating functions, will be published elsewhere, but a result relevant here is that if a number of particles are released in a plane at time $\tau = 0$ and the distribution of their distances from this plane is Gaussian with variance $\beta\tau$ after a time τ , β being a constant—so that, if their mean moves with constant velocity ω , the seminvariant-generating function of their displacements (x) from the original plane is $\eta(-\omega t + \frac{1}{2}\beta t^2)$, which is equal to $\eta F(t)$, say—

then the seminvariant-generating function of the times (y) taken by the individual particles to reach a parallel plane at a distance ξ is

$$\xi F^{-1}(t) = \xi(\omega - \sqrt{\omega^2 + 2\beta t})/\beta.$$

The corresponding distribution function has been given by Schrödinger³ and Smoluchowski⁴, who derived it by a different method. The coefficients of variation of x and y are equal when $\xi = \eta\omega$.

In general, if a variate x has the seminvariant-generating function $\alpha L(t)$, and another variate y the seminvariant-generating function $\beta L^{-1}(t)$, then their means are respectively αx_1 and β/x_1 and their variances αx_2 and $\beta x_2/x_1^3$, where x_1 and x_2 are the first and second seminvariants of the seminvariant-generating function $L(t)$. The coefficients of variation are equal if $\beta = \alpha x_1$, so that the mean value of x is β , while that of y is α . Thus, when the seminvariant-generating functions of x and y are so related, and the accuracy is measured by the coefficient of variation, y/β is as accurate an estimate of $1/x_1$ as x/α is of x_1 . Further, if the coefficient of variation is small, it is approximately the same for β/y , which is therefore as good an estimate of x_1 as x/α . I suggest that two variates related as x to y should be termed *inverse variates*, and either distribution may be said to be the *inverse* of the other.

I have been able to prove that the seminvariant-generating functions must be related in this way in the case of the Brownian motion problem, even when the latter is generalized by the removal of the assumption that the particles spread out on either side of their mean in a Gaussian manner. On the other hand, I have not been able to formulate a general sampling rule by which the inverse variate can be obtained from a given group of distributions, so that the definition of inverse variates remains a relation between their seminvariant-generating functions and between their means.

MR. TWEEDIE's demonstration of the relation between the seminvariant-generating (or cumulant-generating) functions of two sets of related distributions is of great interest. However, the word "inverse" is already used in statistical theory, first in the phrase "inverse probability", and secondly in connexion with the problem of finding a distribution with a given characteristic function. If it is used in yet a third sense, some confusion may possibly arise, although "inversion" is already used in geometry and algebra with different meanings, and without inconvenience. It may be added that Mr. Tweedie's letter does not give an alternative solution of the problem raised by my own, since I am concerned with the distribution, not of n , but of $\frac{R-1}{n-1}$, which gives an unbiased estimate of the probability π .

Bacteriological Studies of Pinosylvine, its Monomethyl and Dimethyl Ethers, and Toxicologic Studies of Pinosylvine

CONTRARY to what is true of sap-wood, pine heart-wood cannot be digested by the normal sulphite method. The cause of this has often been discussed. Investigations, especially by Hägglund and his co-workers, eventually disclosed that the cause must lie in the presence of certain substances in the heart-wood which can be extracted by suitable solvents.

In 1939, Erdtman isolated from such extracts two phenol substances which had not been described earlier, namely, pinosylvine (*trans*-3:5 dioxystilbene, $C_{14}H_{12}O_2$), and its monomethyl ether (*trans*-3-oxy-5-metoxystilbene, $C_{14}H_{11}O(OCH_3)$). The name is derived from *Pinus sylvestris*.

The physiological importance of the pinosylvine substances lies in the fact that they protect the dead heart-wood against wood-decaying fungi and insects. Pinosylvine is closely related to resorcin and its derivatives, 4-hexyl-resorcin being a well-known antiseptic. Pinosylvine may therefore be expected to have a bactericidal effect. Its toxicity was already observed by Erdtman in one of his experiments. He released some aquarium fishes, *Lebistus reticulatus*, in a weak solution of pinosylvine (0.002 per cent). The fishes died rapidly.

The toxicity of the pinosylvine substances in relation to wood-decaying fungi was investigated by Rennerfelt in 1943. Jorpes has tested the oestron effect of pinosylvine, this in view of its relationship to stilbene, but he could demonstrate no such effect.

As no bacteriological and no additional toxico-

Penicil.	Staphyl.
Subtil.	Tryph.

Pinosylvine and pinosylvine monomethyl ether are thus derivatives of stilbene and belong to a group of natural products which is as yet very small. Like stilbene, pinosylvine displays a bright violet fluorescence in ultra-violet light. Pinosylvine is very difficult to dissolve in water, its monomethyl ether still more so. On the other hand, these substances are easy to dissolve in alcohol, acetone and ether. The dimethyl ether is practically impossible to dissolve in water. The melting point of pinosylvine is $156^{\circ}C.$, that of its monomethyl ether $122-123^{\circ}C.$

logical studies have been made of the pinosylvine substances, the accompanying table gives a summary of my investigations carried out during 1943-44.

The table demonstrates the bactericidal effect of pinosylvine and its monomethyl ether as compared with that of phenol.

The accompanying figure shows the bactericidal effect of different concentrations of pinosylvine on bacteria cultivated on agar.

A summary of the results of all the bacteriological studies made of pinosylvine substances discloses that

		1 500	1 1,000	1 2,000	1 5,000	1 10,000	1 20,000	1 50,000	1 100,000	Aq.
Pinosylvine	<i>B. staphyloc. aureus</i>				—	—	±	+	+	
	<i>Penicillium</i>				—	—	±	+	+	
	<i>B. subtilis</i> (spores)			—*	+	+	+	+	+	
	<i>B. typhi murium</i>				+	+	+	+	+	
Monomethyl-ether	<i>B. staphyloc. aureus</i>				—	—	±	+	+	
	<i>Penicillium</i>				—	—	±	+	+	
	<i>B. subtilis</i> (spores)			+	+	+	+	+	+	
	<i>B. typhi murium</i>			+	+	+	+	+	+	
Phenol	<i>B. staphyloc. aureus</i>	—	—	±	+	+	+			
	<i>Penicillium</i>	—	±	±	+	+	+			
	<i>B. subtilis</i> (spores)	—	±	±	+	+	+			
	<i>B. typhi murium</i>	—	±	±	+	+	+			
Aq.	<i>B. staphyloc. aureus</i>									+
	<i>Penicillium</i>									+
	<i>B. subtilis</i> (spores)									+
	<i>B. typhi murium</i>									+

* In earlier experiments.

the inhibiting and bactericidal effect of pinosylvine is 7-30 times as strong as that of phenol in respect of *B. typha murum*, about thirty times as strong in respect of *B. staphylococcus aureus*, and about forty times as strong in respect of spores of *B. subtilis*. The inhibiting and bactericidal effect of pinosylvine monomethyl ether is about three times as strong as that of phenol in respect of *B. typha murum* and about ten times as strong in respect of *B. staphylococcus aureus*. Pinosylvine dimethyl ether, finally, has no demonstrable bactericidal effect, probably owing to it not possessing any group of free hydroxides. Pinosylvine and its monomethyl ether thus appear to possess the strongest bactericidal qualities hitherto demonstrated in any phenol compound found in Nature and isolated.

The toxicological investigations showed that the minimum lethal dose, calculated for a mouse of 15 gm., is 1-2 mgm pinosylvine in a 10 per cent alcohol solution, injected intraperitoneally. For the sake of comparison it may be mentioned that the corresponding value for phenol in water is 2.5 mgm injected subcutaneously. The toxic effect of pinosylvine is thus stronger than that of phenol and at the same time the poisoning symptoms are different, there being no convulsions.

Details of this work will be published in the *Nordisk Hygienisk Tidskrift*.

Effects of Thiourea and Allylthiourea on the Germination of the Seed of *Striga lutea*

Striga lutea is a parasite belonging to the Scrophulariaceae which attacks the roots of a number of crop plants. As with some other closely allied species, the seeds will germinate normally only after exposure to a stimulant produced by a host root¹. Observations, however, on the effects on germination of a series of substances known to have biological activity in other connexions indicate that the host stimulant may be replaced, to a limited extent, by certain comparatively simple compounds. The experiments in which these observations were made involved incubating parasite seeds at 22° C for twenty-one days on moist filter paper, transferring them to another culture vessel provided with filter paper moistened with a solution of the experimental substance, incubating for a further period of some days at 22° C, and finally exposing the culture to 34° C for 24-48 hours. Thus the experimental process embodied three separate phases, each necessitated by a particular condition, the first by the fact that the parasite seed reacts vigorously to the host stimulant only after exposure to moisture for some days, the second by the effect of immediate exposure to the higher temperature with the substitute stimulant, which is that of inhibiting-germination, and the third by the fact that neither with the normal nor with the substitute

stimulant does extensive germination occur at the lower temperature, however prolonged is the period of incubation.

The effects of some forty-two compounds were examined, and of these only two—thiourea and allylthiourea—promoted any germination in the absence of the host stimulant. Thiourea was the less effective of the two, by treating the seed with a 1 per cent solution for three days in the second phase, and afterwards incubating for twenty-four hours in the third, a percentage germination of 36.9 was obtained. This, however, was an exceptional result, a variety of other treatments was tried, but they all gave considerably lower values.

The results in terms of percentage germination of an experiment with allylthiourea, in which the variables were solute concentration, the duration of the second phase, and the duration of the third, are given in the accompanying table.

Clearly the effect of the higher concentration is more rapid than that of the lower in that it yields the highest germination with two days, whereas the lower does so with five days of second-phase treatment. With both concentrations germination increases as the third phase is extended from twenty-four to forty-eight hours, and with both, prolongation of the second phase after a peak value is reached tends to depress germination. The effect of allylthiourea may be compared with that of the natural stimulant. Seeds exposed to the same treatment in the first phase as were those with which the values of the table were obtained gave after exposure to a host stimulant solution for six hours, followed by incubation with distilled water at 34° C for twenty-four hours, a percentage germination of 80.6. The treatment with the host factor for six hours corresponds to the second-phase treatment with the substitute, which extends over days. The concentration of the host stimulant used was unknown, but certain evidence suggests that it was certainly not greater than 1 part per 1,000,000. Thus, not only does the normal stimulant yield a higher percentage germination, but also it is effective at a very much lower concentration and acts very much more rapidly than allylthiourea. The differences are undoubtedly great, and they suggest corresponding differences in the chemical characteristics of the natural and substitute stimulants.

The present series of results are of some significance in relation to earlier reports on the breaking of dormancy in potato buds², maple seeds, acorns³ and lettuce seeds^{4,5,6} with thiourea and in lettuce seeds with allylthiourea⁴. In particular it may be noted that Thompson and Kossar, and later Rayleigh, found that thiourea has an inhibiting effect on the growth of the seedling, which according to the latter is avoided by washing the seeds after treatment for some hours with the stimulant. In the course of the present investigation a similar phenomenon has also been noticed. The effect of both substances is apparently twofold, at certain concentrations germination is induced, but although the seed coat is broken by a slight extension of the radicle, the latter, instead of

Duration of 2nd phase in days	1		2		3		4		5		6	
Duration of 3rd phase in hours	24	48	24	48	24	48	24	48	24	48	24	48
1.0 per cent solution	56.6	64.5	57.5	68.3	45.7	54.3	47.3	58.9	3.5	8.1	4.1	7.3
0.1 per cent solution	3.2	5.9	2.3	4.8	43.5	52.3	48.3	62.1	51.8	58.5	25.3	38.3

elongating, tends to form a spherical mass of tissue to which longitudinal growth is restored by washing the seeds in distilled water. In these cases growth is inhibited, but in certain others an inhibitory effect on germination itself may also be demonstrated. With prolonged exposure to the stimulant in the second phase, as indicated by the data presented above germination tends to decrease, but here again washing the seeds before exposure to a higher temperature in the third phase frequently restores a high percentage germination to the sample.

The similarity between the effects of the two substances on the development of dormant organs, and on the germination of the seed of *Striga lutea*, suggests a corresponding similarity in the internal conditions of the dormant organs and of the parasite seed before exposure to the host stimulant. On the other hand, it must be emphasized that the similarity is not close, since many substances which break dormancy have no effect on the parasite seed. For example, while Thompson and Kossar found that thiosemicarbazide, thioacetamide, ammonium thiocyanate, and potassium thiocyanate were also effective in inducing germination in dormant lettuce, the same substances have no effect with the seed of *Striga lutea*.

Purification of Anterior Pituitary Corticotrophic Hormone

IN the course of attempts to purify the corticotrophic hormone of the pituitary anterior lobe in the past few years, it was noted that the corticotrophic hormone shows far greater solubility in alcohol than other pituitary anterior lobe principles, it was also found to be more thermostable. Fresh pituitaries were therefore refluxed with ten times their weight of absolute ethyl alcohol (final alcohol concentration about 95 per cent) at pH 5. Such extracts gave a far higher yield of corticotrophic activity than any other extraction method previously employed, but the most interesting fact found in connexion with the hot alcoholic extraction of the glands was that, on being filtered and cooled, the extract deposited a considerable amount of solid matter which quickly settled. The corticotrophic activity of both the supernatant fluid and of the deposit were estimated by the method of Reiss *et al.*¹ A considerable amount of corticotrophic activity was found in the fluid, but it was of particular interest that the acetone-dried deposit contained an unexpectedly high amount of corticotrophic hormone. Other anterior pituitary biological activity could not be found.

The supernatant liquid yielded—after concentration *in vacuo*—a further amount of solid material, which was also found to have a high degree of corticotrophic activity. We deduce, therefore, that the corticotrophic fraction is comparatively very soluble in warm alcohol, but sparingly soluble in cold alcohol.

The advantage of this method of purifying the corticotrophic principle would seem to be that an active corticotrophic hormone fraction is obtained which contains relatively little inert material or other anterior pituitary hormone.

The acetone-dried deposit can be completely dissolved in warm glacial acetic acid and such a solution forms on cooling, a partly crystalline precipitate. The further fractionation of the partly crystalline material and the investigation of its biological activity are being carried out.

Possible Synergistic Effect of Cod Liver Vitamin D on Synthetic Vitamin D₃

Stott and Harris suggest¹ that "when synthetic vitamin D₃ is blended with cod liver oil the assay, in international units, is higher than the calculated figure", and cite two typical results of tests using eighteen pairs of rats in each assay. They also cite the average figures for thirteen blends of cod liver oil, but there is some ambiguity as to whether the averages also apply to the calculated and ascertained potencies of the resulting mixtures.

While their conclusion is of course not impossible, prudence would suggest that if it is to be generally accepted, further and more precise data should be provided. Although it is clear from the context that the biological tests used depend on the cure of experimental rickets in the rat, the authors do not mention the precise method used.

Assuming either of the British Pharmacopoeia methods to have been used, the fiducial limits at $p = 0.99$, using ten pairs of rats, may be as wide as 49–215 per cent², but much will obviously depend on the precision attained in Stott and Harris's own laboratory. No indication of this is given. The point is of especial importance because no fewer than three biological assays enter into each comparison, namely, assays of the original oil, the vitamin D₃ concentrate and the final mixture.

With fiducial limits of the order of those cited in the British Pharmacopoeia—which may be even wider in the tests under discussion—it is obvious that many repetitions would be needed before an interesting possibility could be regarded as a statistically significant finding.

Further information should also be provided as to the genesis of the figures for the "synthetic vitamin D₃". This is presumably the commercial product which is, strictly speaking, not synthetic at all and which is normally assayed and sold—as required by law—in terms of B.S.I. units, not in terms of international units. Stott and Harris's use of the term 'international units' in this context presumably implies that they have re-assayed it on rats before use. If so, it would be of interest to see a comparison between the assay in B.S.I. units, on which the concentrate was purchased, and their assay in international units. If, on the other hand, no re-assay has been carried out, then the use of the term 'international units' is not justified.

In this latter contingency, the possibility of an under-estimate of the potency of the vitamin D₃ concentrate is by no means negligible. The B S I test—with or without minor modifications—has been carried out in these Laboratories for the past eight years, and I am indebted to my colleague, Dr M D Wright, for the information that the accuracy normally attained is indicated by fiducial limits at $p = 0.99$ of approximately 75–133 per cent. It is, therefore, possible—especially in view of the strict legal requirements as to potency declarations associated with these oils—that the vendor of the 'synthetic' vitamin D₃ may have deliberately sold it on the basis of a very conservative estimate of potency. It is suggested herefore that before Stott and Harris's conclusions are generally accepted, much more detailed information should be provided by them on this and the other points raised.

Pollen of Lime (*Tilia* spp.)

POLLEN production in small-leaved lime (*Tilia cordata* Mill.), as the following figures show¹, is comparable with that of durmast oak (*Quercus petraea* Liebl.)

Pollen output	<i>Tilia cordata</i>	<i>Quercus petraea</i>
Single flower	43,500	41,200
Ten-year-old branch system	89×10^4	111×10^4
Total for a pure stand 100 × 100 m	$5,600 \times 10^4$	$3,500 \times 10^4$
50-year total for a similar stand	$280,490 \times 10^4$	$34,410 \times 10^4$

Oak is a typically anemophilous tree, and its pollen production in certain years at least is well known to be correspondingly high—the figures therefore need no comment. Two other groups of facts bear out the importance of pollen production in *Tilia*.

(1) Lime pollen occurs in quantity in English and Welsh peat deposits covering a long period of post-glacial time, and its presence in substantial proportion is held by Godwin² to characterize the warmest phase of that period. Pollen analysis of a peat from the East Moors, Cardiff³, showed that at one horizon 3 per cent of the total tree pollen was lime.

(2) Lime pollen is present at certain times in considerable quantity in the atmosphere near lime trees and can be caught on adhesive surfaces exposed in the vicinity. Thus the following quantities of *Tilia* and other pollen (mainly grass) respectively were caught on 5 sq cm of a slide exposed horizontally on the roof of the National Museum of Wales, Cardiff (10 ft above ground) on the dates stated⁴: 1942, June 29–July 1 (48 hours), *Tilia* 174, other pollen 34; July 1–2 (24 hours), 274 and 222; July 2–3, 9 and 306; 1943, June 30–July 1, 34 and 97. Similar counts were obtained from slides exposed for 24 h, by the courtesy of Prof F T Brooks, on the roof of the Botany School, Cambridge, in 1943, namely, June 26–28, *Tilia* 173, other pollen 193; June 28–29, 36 and 60; June 29–30, 66 and 94.

So far from producing little pollen (as claimed by Yate Allen in the statement quoted by Mr

Cartwright Farmiloe⁵) lime seems to be an outstanding example of a plant which, notwithstanding the fact that its flowers produce nectar and are regularly visited by insects in consequence, yet produces and sheds also an abundance of pollen.

Naga, Naja, Naia or Naya?

In paragraph 19 of the review in *Nature* of October 21, 1944, of "The Fauna of British India", Colonel Wall states: "The generic name of the cobra should be altered to *Naga*. It was clearly the intention of Linnaeus to attach to it the name by which it is universally known to the natives of India—'nag' (pronounced narg). It is probable that this information was conveyed by letter and that he mistook the 'g' for 'j'. *Naya*, and still less the *Naia* of some authors, have no meaning."

The two common Singhalese names for cobra are 'nāgayā' and 'naiā', or more correctly, 'nayā', and if, as Colonel Wall states, it is probable that Linnaeus's information was conveyed to him by letter and that he mistook a 'g' for a 'j', is it not equally probable either his correspondent considered 'j' and 'i' interchangeable, as has been customary, or that he actually wrote 'y', which Linnaeus mistook for 'j'?

'Naja' has certainly no meaning to a Singhalese, but 'naiā' or 'nayā' will make him jump.

P J. Kipp

THE description by the author of a recent communication¹ of the apparatus for the continuous generation of gases at the ordinary laboratory temperature as a 'kip' is almost an insult to the work and memory of P J Kipp². This eminent Dutch chemist was born more than a hundred years ago at Delft, where he founded the well-known firm of P J Kipp and Sons to which many chemists and physicists have been, and hope to be again, indebted for beautifully made scientific apparatus. A representation of Kipp's apparatus is incorporated in the seal of the Dutch Chemical Society.

We have become accustomed to the abbreviation of the name of the familiar burner as a 'Bunsen' and we may speak of Kipp's apparatus as a 'Kipp', but I, for one, hope it will never be described again as a 'kip'.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN AUSTRALIA

THE seventeenth annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia*, covers the year ended June 30, 1943, in which the total expenditure of the Council was £541,283, of which £106,126 was contributed from sources other than the Commonwealth Treasury. A large part of the Council's activities is now devoted to the solution of problems arising out of the War and to assistance and advice to Government Departments and other institutions and organizations concerned with the war effort, particularly the work of the National Standards Laboratory and the Departments of Aeronautics, Forest Products and Industrial Chemistry. Reference to these activities in the report is either confined to brief general statements or entirely omitted.

The work of the Division of Plant Industry followed the lines of last year. The Division continued to prosecute investigations leading to the production of essential drug plants, including those on poppy, pyrethrum, cinchona, *Duboisia* and *Ephedra*. In this work the Medical Equipment Control Committee of the National Health and Medical Research Council, the Department of Pharmacy, University of Sydney, the Physiology Department of the University of Melbourne, and the Forestry Department of Queensland are co-operating. Special attention is being paid to studies of plants likely to serve as a source of rubber, particularly to guayule and *Taraxacum koksaghyz*. Work is being continued on microbiological retting of flax, with some interesting results which may have an important bearing on the process. In spite of great difficulties owing to the shortage of seed and increased requirements, the Commonwealth Vegetable Seeds Committee, set up in January 1942, operated under the chairmanship of the chief of the Division until January 1943, and the foundations have been laid for the development of a permanent industry.

Entomological investigations carried out for the medical branches of the Fighting Services have been very fruitful. Valuable practical results have come from the studies of the insect pests of stored wheat and wool. The work on insect pests of stored wheat has covered control measures in bulk depots, the fumigation of bag-sacks and the sterilization of stack sites. In testing some Australian nitrated cresols, it was found that mineral oil emulsion containing 5 per cent commercial grade dinitro-o-cresol was comparable in toxicity with the proprietary emulsion. Fumigation experiments have been carried on with the view of selecting material for use as sprays or solid fumigants against infested stacks of stored wool, and a nozzle has been designed which enables satisfactory distribution of liquid sprays to be obtained within a wool stack when used in conjunction with a jetting plant, and a technique for spraying stacks from above has been devised. The potato moth caused severe crop losses on the mainland during 1942-43, and experiments were carried out with a number of materials used as sprays for the control of potato larvæ in the haulms in the field, basic copper arsenate giving the most promising results.

In the field of animal health and nutrition more attention has been given to the immediate needs of the animal industry and to the application of exist-

ing knowledge to prevent waste. Investigations at the Animal Health Research Laboratory, Melbourne, have covered pleuropneumonia of cattle, mastitis in dairy cattle, contagious abortion, a study of the mechanics of hand-feeding sheep, and the toxicity of wheat for stock. The McMaster Animal Health Laboratory has continued its studies of phenothiazin in the control of nodular worm and of the large stomach worm in sheep, as well as its work on dipping and dipping. The study of the physical properties of wool has been interrupted, but in the field of wool biology further advance has been made towards establishing a method of analysis by which the many sources of biological variation within and between fleeces can be studied under well-controlled and uniform conditions. The Animal Nutrition Laboratory, Adelaide, has brought its investigations on energy metabolism of sheep to a stage ready for preparation for publication as a scientific monograph.

The work of the Division of Soils in the first half year was largely concentrated on defence projects and field surveys of laboratory research have been restricted through lack of staff. The main change has been the initiation of a programme of investigations in soil mechanics, principally concerning soil cement, which it is proposed to continue as a major project. Investigations on the stabilization of soils with pure calcium chloride showed that dressings of 1 to 6 lb pure calcium chloride per square yard were insufficient to stabilize soils in inland southern Australia under concentrated traffic. The Commonwealth Research Station at Merbein, Victoria, was established primarily to investigate problems associated with the production and processing of dried fruit, including irrigation of the land and maintenance of soil fertility. Some of the investigations have been suspended during the last two years and replaced by investigations dealing with special war-time requirements, but the experience of the Station in primary production under irrigation conditions and in drying foodstuffs is being fully utilized by the Commonwealth Department dealing with the processing and storing of dried fruits and vegetables and in the production of special crops not previously grown in commercial quantities in Australia. Fruit drying investigations have now been extended to practically all dried fruits required by the supply authorities. The Station has assisted in the development of about 500 acres of land brought under irrigation since the outbreak of war. The plants grown include vegetables at military establishments, grass covers for aerodromes and drug plants. The Irrigation Research Station at Griffith, New South Wales, established in 1924, has been considerably expanded owing to pressing problems in maintaining the production of fruit and increasing that of vegetables. The long-term citrus cover-crop plants at the Station have demonstrated the value of lucerne in controlling excess soil moisture, salt and structural deterioration. Vegetable investigations have been concerned mainly with irrigation, the germination of seeds, particularly of carrots, and weed control. The Station has also assisted in defining soil and slope suitability standards as a guide to the use of land for citrus.

The main activity of the Division of Forest Products has continued to be advisory work for the various branches of the Services and industry. Steady progress has been made in investigations basic to aircraft production, such as the development of improved wood and the use of timbers for aircraft plywood other than those already approved. Problems

* Seventeenth Annual Report of the Council for Scientific and Industrial Research, for the Year ended 30th June 1943. Pp. 76 (Canberra: Commonwealth Government Printer, 1944.) 3s. 4d.

rising out of the treatment of timber to fit it for use in tropical areas are under investigation. New laboratories have been erected for paper-testing work and for flax, but much experimental work is awaiting development in connexion with the newer types of synthetic resin glues and methods of plywood manufacture and use.

The work of the Division of Food Preservation and Transport has also been almost entirely devoted to problems of direct importance in the war effort. The canning and dehydration of foodstuffs continue to be the most important fields of investigation for the Division. The Meat Investigation Laboratory at Brisbane has been concerned chiefly with dehydrated beef, and the investigations have led to a closer definition of ideal processing conditions and may reduce processing costs. Particular attention has been given to the improvement of flavour. In work in storage it was observed that the dried meat is very subject to infestation by a beetle, *Dermestes ulpinus*. Other investigations have covered a survey of the vitamin C content of tomato varieties grown in the Bathurst district and of the vitamin C content during the processing of canned tomatoes, tomato juice and tomato puree. Meat-canning investigations have also assisted with production programmes, and container investigations have led to the development of technique and equipment for the rapid testing of cans. An attempt has been made to obtain fundamental data in this field, including studies of the effect of variations in template thickness on closing-machine adjustments. Experiments to determine the storage life of different samples of dried egg under various conditions have continued, but the storage experiments on dried mutton have been completed. The Microbiological Section has been concerned almost entirely with canned foods and investigations on eggs. Fruit-storage investigations have included skin coatings on apples, the best results were obtained by hand dipping the apples in an alcoholic solution of 8 per cent castor oil and 2 per cent of de-waxed shellac. The treated fruit was less wilted, firmer, crisper and more juicy and the flavour and acid were retained longer. Wax emulsions are more effective than oil emulsions in retarding loss of moisture, but require higher concentrations and more alkaline soaps. The Fruit Products Section has been largely responsible for organizing the large-scale production in several States of canned and bottled citrus juices for antiscorbutic purposes in Service rations. The production of canned apple juice fortified with synthetic vitamins was also commenced in New South Wales and Tasmania, and research has been carried out on substitute containers, the smoke curing of fish, and electrical moisture meters.

The Fisheries Investigations Division carried out a comprehensive survey of the fishing industry for the man-power authorities, and technical work connected with the manufacture of agar was done in conjunction with various firms interested. An extensive survey of seaweeds suitable for this purpose is at present being carried out by the Division. A pilot plant for the manufacture of sodium alginate, potash and iodine is working in Sydney. Livers of twenty species of shark and ray have been examined for oil and vitamin content in an effort to find livers rich in vitamin A and possibly vitamin D to augment supplies being used in Victoria. The withdrawal of the research vessel *Warreen* from service during the year broke the continuity of the tuna observations on the south-east coast.

In the Industrial Chemistry Division, the Biochemistry Section continued research designed to assist the fellmongering industry, while the Minerals Section assisted in the commercial utilization of Australian minerals by devising and adopting chemical treatments necessary for the manufacture of a wide range of chemical compounds from crude ores and minerals, chromite, monazite, fluorite, bauxite, graphite, pyrolusite, rutile, beryl and rock phosphate received the main attention during the year. The whole of the research work in physical metallurgy of the Divisions of Industrial Chemistry and Aeronautics has now been consolidated in one Section of Physical Metallurgy, included for administrative purposes within the Division of Industrial Chemistry.

The Organic Chemistry Section has constructed and operated a pilot plant for the manufacture of ethylene. A pilot plant is also being constructed for the manufacture of ethylenedichlorohydrin by a continuous process. Preliminary preparations of a synthetic rubber of the 'Thioplast' type have been made, and phenol and cresol-formaldehyde resins have been investigated to discover resins suitable for the production of compressed woods and as hot glues for plywoods, compressed woods, and wood-metal joints. A method of analysis developed in the laboratory gives valuable information when applied to resins of outside origin. Resins of the aniline/formaldehyde type are also being developed as moulding powders for some electrical work and as adhesives for compressed woods. Surplus fatty acids have been examined as possible sources of substitute waxes, and a method of estimating the mannitol in the exudation from trees, *Myoporum platycarpum*, has been completed, and the isolation of the material on a pilot-plant scale is under investigation. The section concerned with lubricants and bearings have been engaged primarily on confidential war work.

The Information Section has made a distinct contribution to the war effort in the preparation of summaries and bibliographies connected with aspects of technical productions, and in the compilation of information on the substitution of Australian raw materials for materials formerly imported. Officers of the Section have continued to act as an abstracting panel for the preparation of *Australian Chemical Abstracts*, published by the Australian Chemical Institute, which are confined entirely to reports and articles published in Australia, and to Australian patents.

PENICILLIN TREATMENT OF VENEREAL DISEASE AND SPIROCHÆTAL INFECTIONS

THE remarkably successful treatment of gonorrhoea with penicillin was recorded in an earlier note on penicillin treatment (*Nature*, 677, Nov 25, 1944). In that note also the opinion of United States Army medical men that the immediate effects of penicillin in the treatment of syphilis are better than those of arsenical preparations was recorded. Leading articles in the *Lancet* (853, Dec 30, 1944) and the *British Medical Journal* (821, Dec 23, 1944) discuss the whole question of penicillin treatment of human syphilis, with references to the relevant literature.

In the United States the first experiments on this problem were done on rabbits infected with syphilis, and J. F. Mahoney, R. C. Arnold and A. Harris

(*Ven Dis Inform.*, 24, 355, 1943) were apparently the first to record penicillin treatment of human syphilis. In Britain, E M Lourie and H O J Collier (*Ann Trop Med and Parasitol*, 37, 200, 1943) showed that penicillin will cure infections of mice with *Treponema recurrentis* and *Spirillum minus*. In co-operation with A O F Ross and R B Wilson (*Lancet*, 845, Dec 30, 1944) they report on the treatment of five cases of human syphilis with penicillin. All these cases had well-marked secondary lesions, and the immediate response "could not have been bettered by any known form of treatment". The spirochaetes and lesions disappeared at least as rapidly as they do under treatment with arsenicals and bismuth. But all these cases were in the secondary stage of the disease, and later observations upon them showed that only one of the five cases was apparently cured. It was therefore doubtful whether penicillin was as beneficial as arsenicals and bismuth would have been. These authors concluded that penicillin will not become suitable for routine civilian practice until frequently repeated day- and night-injections can be avoided.

The problem of dosage in the treatment of syphilis is discussed by both the *British Medical Journal* and the *Lancet* (*loc cit*). In the United States, where so much more penicillin is available, extensive trials of it for the treatment of syphilis have been going on at thirty-one centres, and the *Lancet* discusses the reports on these and the supply of penicillin, stating that, by April 1944, the tentative production programme of the United States and Canada was, according to R. D Coghill (*Chem Engineer. News*, 22, 588, 1944), of the order of 200,000 mega units (1 mega unit is 1 million Oxford units). There will be general agreement that we are justified in expending a large proportion of even the limited British supplies of penicillin on the study of its effects on syphilis. Arsenical treatment is more toxic and is not infallible, it involves supervision of the patient for a year or longer, and J Marshall (*Nature*, 153, 187, 1944) has pointed out that less than half the patients get enough of such treatment to ensure a cure-rate of 80 per cent, because they default. One danger of future penicillin treatment is emphasized by both the *Lancet* and the *British Medical Journal* (*loc cit*). A patient may have both gonorrhoea and syphilis at the same time. The gonococcus is more susceptible to penicillin than the spirochaete of syphilis. Treatment with doses of penicillin which are sufficient to cure the gonorrhoea may therefore suppress the early signs of the syphilis, without being sufficient to cure this disease, especially if the syphilis is at an early stage when the only sign of it may be a hidden chancre. The diagnosis of syphilis may therefore be only made later when the secondary signs appear. F L Lydon and W R S Cowe (*Brit. Med J*, 110, Jan 27, 1945) also discuss this subject, adding the point that battle casualties treated with penicillin for gonorrhoea, for which it is, they agree, the drug of choice, may be incubating syphilis as well, which would thus escape detection. They think that routine blood-tests should be enforced by law upon the whole population. Similar cases of coincident infections with these two venereal diseases are discussed by F A Ellis (*J Amer Med Assoc*, 126, 80, 1944) and by C R Wise and D M Spillsbury (*Brit J Surg*, 32, 214, 1944).

Penicillin seems to be very effective also against other spirochaetes and their relatives. Brigadier G M Findlay, Major K R Hill and A Macpherson (*Nature*,

795, Dec 23, 1944) report some success in the treatment with penicillin of yaws, due to *Spirochaeta penae* and of tropical ulcers infected with spirochaete fusiform bacilli and other organisms. Ulcers have caused, during 1944, the loss of 30,000 men-days among West African troops. A B MacGregor and D Long (*Brit Med J*, 686, Nov 25, 1944) report the rapid disappearance of *Treponema vincenti*, the cause of Vincent's gingivitis, under treatment with penicillin incorporated in pastilles. J M Alston and J Broom (*Brit Med J*, 718, Dec 2, 1944) report their experiments on its action on nine strains of *Leptospira icterohaemorrhagiae*, the cause of Weil's disease (six strains were human, two were from rats and one from a dog) and on one strain of *L. canicola*, the cause of another form of leptospiral infection in man and dogs. Penicillin killed all these strains in cultures and also inhibited their multiplication. It also cured infections of guinea pigs with leptospira virulent to them, provided that it was given early enough (eighteen hours after infection). It did not prevent the development in the guinea pigs of serum antibodies or resistance to re-infection. It was not toxic to the guinea pigs as others have reported to be. In the same issue of the *British Medical Journal* (p 720), V Lloyd Hart reports upon the treatment of one Italian male suffering from Weil's disease. The results suggest that even the very small dose given at relatively long intervals, had some curative effect, but Hart also emphasizes the need for early administration. It is, however, difficult to diagnose Weil's disease in its early stages. The same necessity for early administration is emphasized by B E Bulmer (*Brit Med J*, 113, Jan 27, 1945) in his summary of the treatment by various medical officers of sixteen cases of the same disease in Normandy. It is thought that Weil's disease is spread by infected rats, which pass the spirochaetes in their urine. The spirochaetes can live for a time in stagnant water wells and sewers, so that men infect themselves by drinking and bathing. Up to December 1944, cases had been notified between mid-July and the end of September, and only from Normandy. It is, Bulmer thinks, surprising that cases have not occurred in the Low Countries, where there is "plenty of water". There was great difficulty in assessing the results of the penicillin treatment. The liver and kidney are rapidly damaged by the spirochaete, so that penicillin should ideally be given before the diagnosis can be made. Inadequate doses of penicillin appeared, however, to shorten the duration of the fever and to cause dramatic improvement, especially when high doses were given. It did not appear to influence the damage done to the liver and kidney. In the same issue of the *British Medical Journal* (p 119), A I Carragher reports on the treatment of one other case, a soldier invalided from France. After only six injections of penicillin the *Leptospira* disappeared from the blood and there was rapid clinical improvement.

Among other organisms of the spirochaete type are *Streptobacillus moniliformis* and *Spirillum minus*, the causative organisms of the two rat-bite fevers. The reasons for the conclusions that two organisms are concerned in the etiology of this disease have been discussed (*Lancet*, 540, Oct. 21, 1944), together with the effect of penicillin on them. F R Heilman and W E Herrell (*Proc Staff Meeting, Mayo Clinic*, 15, 257, 1944) and H Eagle and H J Magnuson (*Pub Health Rep Wash*, 59, 583, 1944) have confirmed the results obtained by Lourie and Collier mentioned

above Heilman and Herrell found that penicillin cured mouse infections with *Sp. minus* and *Strept. moniliformis*, so that both forms of rat-bite fever may prove susceptible to it. The former responds dramatically to organic arsenicals, but the latter resists ursemic, sulphonamides and gold treatment. F. F. Kane (*Lancet*, 548, Oct 21, 1944) reports on the infection of an Ulster boy with *Strept. moniliformis* as the result of a rat-bite, which was successfully treated with penicillin after gold treatment had failed. Eagle and Magnuson obtained cures with penicillin of infections of rats and mice with *Spirochaeta recurrentis* (= *Treponema novyi*), so that it is possible that penicillin may prove better than arsenic for the treatment of relapsing fever of man, which is caused by this organism. G. LAPAGE

FORESTRY AND THE PUBLIC WELFARE

AT the autumn general meeting of the American Philosophical Society held in the hall of the Society on November 17-18, 1944, the first day was devoted to a symposium on "Forestry and the Public Welfare", brief papers being read (among others) on forests in relation to soils and water (Raphael Zon), world-wide needs of woods (W. C. Lowdermilk), public control of cutting practices on private timberland (Joseph F. Kaylor), and forest conservation—public and private co-operation (Wilson Compton).

Zon's research work in connexion with forests, soils and water is well known. He gave a brief summary of important points. The longer precipitation remains in circulation over the land before, as run-off, it reaches streams and ocean, the greater its use to the land. The greatest effect of forests upon water is therefore that they tend to prolong this water-cycle in and in the soil. In deep soils a large reservoir of ground water is retained which only gradually but regularly feeds the streams, thus preventing exceptional high rises resulting in floods, or low levels which diminish agricultural supplies. The protective cover of the forest reduces wind damage, decreases evaporation from the soil, reduces the temperature of the air and soil within the forest during the summer and raises it in winter. Growing trees transpire and thus increase the humidity of the air over forests, while their roots stabilize the soil.

Lowdermilk, in discussing the world-wide needs of woods, pointed out that man has grown up with wood, that he has always utilized the substance in the past, and human progress, in spite of the many substitutes, demands ever larger amounts. Wood, he said, is "a natural wonder of chemistry and physical structure", but cellular structure and chemical content of cell cavities give rise to a wide variety and many properties that serve hundreds of uses, even to paper and clothing fabrics. Modern technology has by special treatment of impregnation and compression produced new materials from wood that compete with metals. Chemical industries are opening up amazing possibilities in deriving from wood as raw material new chemicals based on fermentation of carbohydrates, even to the making of alcohol for rubber manufacture. On the subjects of demand, Lowdermilk said that the production of wood, reported as some 1.2 billion tons, is second only to that of fossil carbonized wood as coal, namely, 1.3 billion tons, and is practically tenfold that of steel.

America has long halted at the cross-roads of State interference in any way with the operations of the lumberman; enormous areas have been felled without a thought to the future, while fire has destroyed additional large areas of virgin forest. In his paper on public control of private felling, Kaylor said that within the last few years sentiment in many parts of the United States has veered strongly towards some form of public control of private felling, the cumulative results of the unrestricted cuttings of the past now being more fully realized. A difference of opinion exists as to whether such control should be exercised by the individual States or by the Federal Government. Kaylor spoke for Maryland, stating that in 1943 the legislature of the State passed the Forest Conservancy Districts Act authorizing a Commission of State Forests and Parks to draw up rules of forest practice for all the privately owned forests of the State—certainly a move in the right direction.

Dealing with public and private co-operation in forest conservation, Wilson Compton discussed briefly the exploitation of the forests in the past and the results of surveys of the forests still existing in parts of the United States and the work of conservation now being carried out. The surveys showed that there are nearly a thousand tree farms comprising 10 million acres in the western and southern States, and the number is being constantly added to. In 1941 the National Lumber Manufacturers' Association co-operated with the forestry departments of thirty-seven States in a survey of 153 million acres of privately owned timber lands—the so-called industrial forest lands, of these, 25 million acres were under working plans, 45 million under less intensive management, another 73 million acres with reasonably satisfactory reproduction, but not adequately protected from fire. In other words, about 94 per cent of the area surveyed was considered to be in a "reasonably productive condition". When the total disregard shown for the immense forest estate exploited by the United States for so long, as if it were inexhaustible, is remembered, it is a good augury that the lumber companies, and to some extent the private forest owner, should have realized where unchecked exploitation was leading the country and its important industries.

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Monday, April 16

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Sir Frank Smith, G C B, G B E, F R S "Chemicals from Petroleum" (Cantor Lectures, 1)

FARMERS' CLUB (at the Royal Empire Society, Craven Street, Strand, W C 2), at 2.30 p.m.—Mr H. W. Grimmer "Present and Future Aspects of Electricity in Agriculture" *

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (CHEMICAL GROUP) (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N W 3), at 7.30 p.m.—Mr B. Chilton "Present-day Problems of Industrial Photography" *

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S W 7), at 8 p.m.—Dr H. L. Richardson "Szechwan during the War" *

Tuesday, April 17

INSTITUTION OF NAVAL ARCHITECTS (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 10.30 a.m.—Admiral of the Fleet the Rt Hon Lord Chatfield, G C B, O M "Presidential Address. Sir Amos L. Ayre, K B E "Merchant Shipbuilding during the War". At 4.30 p.m.—Mr E. H. Watts "Crews' Accommodation in Tramp Ships", Mr A. J. Sims "The Habitability of Naval Ships under Wartime Conditions" *

ROYAL SOCIETY OF ARTS (DOMINIONS AND COLONIES SECTION) (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Dr Charles Cammell "The New Programme of Field Investigation in the Canadian North-West" *

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2), at 2 30 p m—Annual General Meeting, Presidential Address

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Discussion on "Design of Broadcast and Television Receivers for the Post-War Market" (to be opened by Mr L H Bedford)

Wednesday, April 18

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1 45 p m—Sir Edward Appleton, K C B, F R S "The Work of the Department of Scientific and Industrial Research"

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W 1), at 2 15 p m—Discussion on "The Control of Rickettsial Infections" (to be opened by Lieut-Colonel C H Stuart-Harris, Dr J S Carmichael and Dr Raymond Lewthwaite)

INSTITUTION OF NAVAL ARCHITECTS (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 2 30 p m—Mr W Thomson "Some Cases of Failure of Deck Plating due to Stranding", Mr W I Hay "Some Notes on Ships' Structural Members", Mr J M Murray "Notes on Deflected Plating in Compression and Tension" At 4 30 p m—Prof T H Havelock, F R S "Notes on the Theory of Heaving and Pitching", Mr J F Allan "The Stabilisation of Ships by Activated Fins"

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 3 p m—Scientific Papers

INSTITUTE OF PETROLEUM (joint meeting, with the BRITISH RHEOLOGISTS' CLUB) (in the Lecture Hall of the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W 1), at 3 30 p m—Dr A Cameron "Determination of the Pressure Viscosity Coefficient", The Viscosity Panel "Precision and Accuracy of Viscosity using B S I Tubes", Mr E R Pethrick "The Testing of Greases for Ball Bearings", Mr E W Hardman and Dr A H Nissan "A Rational Basis for the Viscosity Index System", Dr A Lahiri and Dr E W J Mardles "The Problem of Engine Deposits", Dr A S C Lawrence "Lubricating Greases"

ROYAL METEOROLOGICAL SOCIETY (in the small Physics Lecture Theatre, Royal College of Science, Imperial Institute Road, South Kensington, London, S W 7), at 4 30 p m—Mr G E R Deacon, F R S "Water Circulation and Surface Boundaries in the Oceans" (Symons Memorial Lecture)

ILLUMINATING ENGINEERING SOCIETY (at the E L M A Lighting Service Bureau, 2 Savoy Hill, London, W C 2), at 5 30 p m—Mr R Maxted and Mr J N Hull "Circuits for Discharge Lamps"

Thursday, April 19

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 11 30 a m—Annual General Meeting At 2 30 p m—Prof W N Haworth, F R S "Starch" (Presidential Address)

ELECTRICAL ASSOCIATION FOR WOMEN (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2), at 2 p m—Twentieth Annual Conference

INSTITUTION OF NAVAL ARCHITECTS (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 2 30 p m—Mr T C Tobin "The Dynamics of Launching", Mr E O Stephens "Thames (Dumb) Barges" At 4 30 p m—Dr G Hughes "On Singing Propellers", Mr V D Naylor "The Concept of Pitch"

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 8 p m—Prof E A Owen "The Silvanus Thompson Memorial Lecture"

Friday, April 20

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 4 45 p m—Dr J F Brailsford "Reflections in the Teaching of Radiology" (Mackenzie Davidson Memorial Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m—Dr L Hartshorn and Mr W Wilson "An Electrical Moisture Meter"

Saturday, April 21

SOCIETY OF INSTRUMENT TECHNOLOGY (at the London School of Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 11 a m

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at Causton Hall, Westminster, London, S W 1), at 2 30 p m—Mr E Mackie "A Consideration of the Requirements for Micrography and Cinemicrography Apparatus"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

LECTURER (full-time) IN ELECTRICAL ENGINEERING—The Principal, Royal Technical College, Peel Park, Salford 5, Lancs (April 21)

CHAIR OF PHILOSOPHY in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W C 2 (April 28)

LECTURER (woman) IN ZOOLOGY—The Principal, Royal Holloway College, Englefield Green, Surrey (April 28)

ASSISTANT LECTURER (temporary) IN MATHEMATICS—The Registrar, University College, Exeter (April 28)

CHIEF ANALYTICAL CHEMIST in the Research Department of a well-known firm in the London area—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3673 XA) (April 28)

SCIENTIFIC OFFICER (CHEMIST, male) at the West Midlands Forensic Science Laboratory at Birmingham—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3859 A) (April 30)

METALLURGIST in the Research Department of a large firm in Yorkshire—The Ministry of Labour and National Service, Appointments Department, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 2721 XA) (April 30)

HEADMASTER OF PERSE SCHOOL—The Clerk to the Governors Montagu House, Sussex Street, Cambridge (endorsed 'Headmaster') (April 30)

SUPERINTENDENT in a Government establishment (candidates should be well qualified in CHEMISTRY or CHEMICAL ENGINEERING, and should have experience in the Manufacture of Explosives and also in the Development of Chemical Processes)—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting Reference No F 3886 A) (April 30)

LECTURER IN MATHEMATICS in the Brighton Technical College—The Education Officer, 54 Old Steane, Brighton (April 30)

LECTURER IN ELECTRICAL ENGINEERING, with qualifications in TELECOMMUNICATIONS and LIGHT-CURRENT ENGINEERING, particularly ELECTRONICS—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S W 11 (May 2)

ASSISTANT LECTURER IN ZOOLOGY, with special qualifications in ENTOMOLOGY or HELMINTHOLOGY—The Secretary, West of Scotland Agricultural College, Blythswood Square, Glasgow (May 5)

GENERAL SECRETARY—The Honorary Secretaries, Chemical Society Burlington House, Piccadilly, London, W 1 (May 15)

ASSISTANT LECTURER IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Liverpool (May 28)

READER IN INDUSTRIAL HEALTH—The Secretary of University Court, The University, Glasgow (June 1)

SHILTO READERSHIP IN ASSYRIOLOGY—The Registrar, University Registry, Oxford (June 9)

UNIVERSITY CHAIR OF BACTERIOLOGY tenable at University College Hospital, Medical School—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (September 24)

ENGINEER to the Ipswich Dock Commission and the Harwich Harbour Conservancy Board—The Clerk and Solicitor to the Ipswich Dock Commission, Old Custom House, Ipswich

LABORATORY ASSISTANT (man or woman, Grade I) IN THE DEPARTMENT OF ZOOLOGY—The Secretary, Bedford College for Women, Regent's Park, London, N W 1

POSTS on the RESEARCH STAFF of the BRITISH COTTON INDUSTRY RESEARCH ASSOCIATION (candidates must possess at least a good Honours Degree and be trained in Chemistry, Physics, Engineering Physics or Mathematics)—The Director of Research, Shirley Institute Didsbury, Manchester 20

LECTURER IN METALLURGY in the Coventry Technical College—The Director of Education, Council House, Coventry

LIBRARY ASSISTANT—The Institution of Automobile Engineers Research Department, Great West Road, Brentford, Middlesex

ASSISTANT SECRETARY (male)—The Secretary, Empire Cotton Growing Corporation, 37 Inner Park Road, Wimbledon, London S W 19

SCIENTIFIC METHOD IN GOVERNMENT

THE Riddell Memorial Lectures entitled "The Unknown State"*, delivered before the University of Durham by Lord Eustace Percy, represent a noteworthy plea for the study of government. They are indeed partly addressed to the scientific worker, and were delivered in the belief that a revival of the neglected study of government is the most urgent need of the present day, and that universities have a special responsibility to make it a learned study. Whether that responsibility can rightly be placed upon the universities is a matter of opinion, but no one who has considered Sir Ernest Barker's views on this problem of government, or J T MacCurdy's suggestive chapters in "The Structure of Morale" or has noted the difficulties into which the administration is being continually led from the Cabinet level downwards for lack of attention to the fundamental machinery of government, can doubt the need for critical inquiry if not independent research in this field, or that such inquiry should be entrusted to an institution of the independent and academic type. The problem appears to lie outside the field of the National Institute for Social and Economic Research, and there is no obvious independent body to which its study could be entrusted.

At the outset of his first lecture, "The Decay of Political Thought", Lord Eustace Percy challenges the indifference of men of science to this problem. He insists that by neglecting it they imperil that freedom of movement, of entrance, and of experiment which they vigorously claim. Having won freedom, man cannot discard philosophy and remain free. His freedom depends upon the constant re-interpretation, in response to changing circumstances, of three fundamental affirmations: that there exists in any human society an authority entitled to over-ride the will of its individual members, that its individual members have, nevertheless, rights which this authority is not entitled to over-ride, and that both authority and individual have positive duties by the punctual performance of which alone the balance of their respective rights can be preserved. The most characteristic symptom of our intellectual failure during the last twenty-five years in Europe and in America to face the implications of freedom has, Lord Eustace suggests, been our attempt to escape from the study of government into the study of some vaguer entity called 'society'. The assumption that human society is either a self-evident entity like the human body, or has been ascertained to be an entity by investigations of its structure as thorough as those of the astronomer or the physicist, is false. Every science which is concerned with the study of individual man is a social science, in the sense that man is a gregarious animal, but in any other sense, Lord Eustace Percy claims that there is only one social science—political science, he regards 'social' medicine, 'social'

* The Unknown State: a Plea for the Study of Government by Lord Eustace Percy (University of Durham Riddell Memorial Lectures) Pp 48 (London: Oxford University Press, 1944) 2s 6d net

biology, for example, as merely those aspects of medicine or biology of immediate concern to governments.

Political science is the study of human beings living in a particular kind of association, called a State, whereby they regulate some part of their conduct in obedience to rules enforced upon them by persons selected for that purpose, in accordance with procedures laid down beforehand. The distinguishing mark of the citizen is that he is the object of regulated compulsion to social behaviour, while the free citizen is distinguished not only by the acceptance of such compulsion but also by sharing, in greater or less degree, in its exercise. Moreover, while the historian must always remember that manhood and womanhood are more wonderful than citizenship, and that men are greater than their institutions, he must not turn truth into falsehood by supposing that they are more social than their institutions.

Lord Eustace Percy then points out that in studying the State we must face the implications of the moral contrast, because the human law of the State does not coincide with the divine law of love. The difference between Christian and civic duty is one of consistent temper rather than of occasional practice. The central assumption of English-speaking democracy is that the citizen must not only be ready to resist general social disorder; he also must think instinctively, even of offences against himself, not as personal injuries, but as threats to the safety of his neighbours. He is not entitled to forgive, and where this civic temper fails, free government breaks down.

Lord Eustace Percy's analysis up to this point shows clearly how easy is the transition from freedom to anarchy, incessant vigilance, clear thinking and a real attempt to grapple with the philosophical aspects will be imperative in addressing ourselves to the tasks of social reconstruction. The divorce of compulsion from responsibility may yet prove the factor to wreck a social security scheme or a full employment policy. Reformers, as he wisely says, can dispense with a philosophy of government only so long as the citizen feels that he is being reformed by his own consent. Once our old catchword of 'government by consent' ceases to describe the citizen's real feelings, he will turn by instinct and tradition from those who govern him to those who offer to govern him on intelligible principles for definable purposes. These principles and purposes must be religious, based upon a coherent view of what man is, of what constitutes for him a 'good life', and of the means by which it can be attained, and in this second lecture, Lord Eustace Percy outlines a Christian philosophy of government. What matters primarily is the spirit of a government and of its citizens, and the practical difficulties are considered of preserving this spirit in a reforming democracy which is also a great international Power.

The statesman, it is pointed out, must work in the medium of social circumstance. Remembering that his fundamental aim is moral improvement, he must judge the probable moral effect upon his citizens, both of law itself and of the processes by which law is made and enforced, given the character of his citizens, the texture of their social system and

the machinery of government at his command. In governing backward peoples, he must be careful not to distort, by novel constraints, the human nature which he can compel, but cannot suddenly change. Compromise is to the statesman what the scientific method is to the man of science; but in politics this scientific attitude has proved unstable.

Christian positivism, Lord Eustace Percy suggests, needs the thought and teaching of universities. Their social surveys at present are providing material for the administrator, not for the statesman, and reflect the contemporary preoccupation with urgent administrative projects, from which emerges no outline of settled law. In his final lecture, he attempts to outline the practical application of his Christian positivism. Here he suggests that under modern conditions of publicity, the tendency of law to create superstitions, and, in its turn, to be itself progressively influenced by such superstitions, has become an imminent danger to the whole system of parliamentary democracy. We need, particularly now, to submit our inherited laws of personal relationships to criticism as keen, and as closely related to the actual facts, as that which Bentham brought to bear on the inherited legal systems of his day, remembering that virtue is a more important fact than vice. The art of government lies, not in continual accretions to law as circumstances or fashions of thought seem to demand, but in those transformations of essence by which the body of the law is kept sound and is made serviceable to the good citizen.

Lord Eustace Percy refers to the point that the only interest which the law recognizes in the shareholder is that of current profit, and in passing to the problem of fitting policy to the facts, he is equally forthright in his challenge to political invention. He emphasizes the danger which lies in the identification of government with the social services, a belief in the efficacy of taxation, and in the efficiency of pure State administration. After the War, a social service policy must, at least, be one of the priorities such as housing, and careful selection. But we must remember that a legislative minimum tends to become a social maximum, and Lord Eustace Percy hopes for the recognition of the family rather than the individual, as the unit of social reform, though it involves a reconsideration of law, a reconstruction of administration, and a regeneration of the spirit of State policy.

In conclusion, Lord Eustace Percy refers to the necessity of overcoming that disabling weakness in the local administration of Britain—the growing inability to combine State and voluntary social services. The most urgent duty of government at this time is that of mobilizing all citizens in the tasks of reconstruction. We have, moreover, to find a way of carrying out social reconstruction without turning every general election and every parliamentary debate into a competitive appeal to majority self-interest. The future task of all law and all statesmanship is to convince men of the inevitability of social change and of its inevitable effect on all lives, to draw from them, in that conviction, the 'free-will

offerings' which alone can bring us safely through such change, and to adapt law and administration fearlessly to such change. Government, like marriage, is a great adventure, but, like marriage, an adventure in the normal architecture of a common life whose temper and whose end is peace, and to both of which the temper of crisis is fatal.

It is remarkable how similar is this philosophical approach in some of its conclusions to those reached by Prof H J Laski from an entirely different angle in his pamphlet, "Will Planning Restrict Freedom?"* Prof Laski argues that planning will be required not merely to renovate the tragedies of war but also to inaugurate that era of scientific research on the threshold of which we stand, and that to give effective expression to the public context in housing and health and nutrition and education, society must plan the use of its resources in peace not less than in war. He examines the argument that in a planned society the citizens must lose that chance to experiment with themselves which is the essence of freedom. Planning, he points out, is simply the exercise of that foresight which adapts the means to the end, but planning evades the dangers of bureaucracy only when the decisions taken by the professional planners are built upon an alert and interested public opinion. A planned society requires from its citizens a higher degree of knowledge, and a far greater continuity of interest than are required in a State where *laissez-faire* obtains, and Prof Laski quotes the experience of the Tennessee Valley Authority which D E Lilienthal brought out so strongly in his recent book.

Prof Laski is thus on common ground with Lord Eustace Percy in urging that decentralization, participation, and a high level of social understanding are the essential safeguards against the danger that a planned society may degenerate into bureaucracy. Decentralization prevents the impress of uniformity in a world where variety is essential for the realization of any scheme of values, participation enables ordinary men and women to play their part in the civic process, instead of leaving their experience to be inferred by leaders. A high level of social understanding is important, first as preventing the division of any society into a small number of persons who rule and a vast multitude over whom they rule, and, secondly, because those who lack a map of the universe in which they dwell are liable to lose their way.

Our task, as Prof Laski sees it, is to discover the institutions through which decentralization, participation, and a high level of social understanding are made generally available to ordinary men and women and he points to three types of experience of which our historic freedom has been the outcome, and which are closely connected with these safeguards against bureaucracy: our emphasis on local self-government, our long experience of ecclesiastical self-government, and, in the last century, our experience in the trade unions and the consumers' co-operative movement. All these point to the existence of a considerable reserve of unused talent, and

it may well be that the joint industrial councils and production committees will provide a potent means of expression in the future which will facilitate that closer integration of industry with the community which is one vital aspect of our problem.

Prof Laski's approach is more pragmatic than Lord Eustace Percy's, but the trend of thought is strikingly parallel. Prof Laski emphasizes the necessity, in developing a system of government, of delineating clearly the responsibility for decisions and of avoiding building institutions which provide ministers and officials alike with an excuse for not taking action. Again, he insists on the need for a massive publicity over the whole field of social action, and on the danger in the assumption by a vast majority of the citizens that political responsibility is not a task in which they ought to share: they must be brought to realize that it is, on the contrary, an integral part of their civic function to shape the character of the political process into which they are born. Once again we find the recognition that, important as is high ability in politics, it is only likely to achieve its appointed aim when linked with integrity and courage.

The central issue in planning is that of eliciting the maximum possible participation of the body of citizens in the processes of politics, and reviewing measures and changes required in the transformation to a planned society. A planned society involves the acceptance of a common body of purposes by its members, and an equal response to equal demands. In saying this, Prof Laski comes closer to Sir Ernest Barker's postulates for democratic government, and to the extent that the totalitarian State represents the spirit and temper of intransigence rather than the spirit of accommodation, Prof Laski might dispute its claims to be a planned society. But there can be no question that in war-time the most successful administrators have been those who most fully took their subordinates into their confidence and sought both to elicit and to use the experience of those subordinates. Firms which had a tradition of good relations with the trade unions have almost invariably a better record of production than firms with a tradition of bad relations. That experience is highly relevant to the future organization of industry, for in industry as in other fields, it remains true that nothing is so important in a society which seeks to remain democratic as the ability to maintain a high interest in its problems among the body of its citizens; and nothing so promotes that high general interest as the pursuit by the community of great purposes which call for the participation of the common man.

Prof. Laski may be rather too facile in his argument, but his pamphlet stresses the essentials clearly enough, though he does not throw down the same challenge to creative thought as Lord Eustace Percy. Without such creative thought, however, we are unlikely to evolve the machinery necessary to serve the needs and purposes of a society determined to achieve the Four Freedoms, and it can at least be said that this pamphlet, like others in the same series,

* Will Planning Restrict Freedom? By Prof Harold J Laski (The Planning Bogies Series) Pp 40 (Cheam Architectural Press, Ltd, 1944) 6d

is a contribution to constructive and unprejudiced thinking about the real issues. The argument, though not the philosophy of Lord Eustace Percy's lectures, has been stated fairly enough often before. It was well put in J MacMurray's "Constructive Democracy", for example, where not only the necessity of government in a true democracy being under effective control was urged, but also the necessity of achieving industrial democracy in order that political democracy may survive. It may be true that, as MacMurray urges, the exclusion of the economic life from the competence of the political authority does not belong to the essence of democracy. Freedom of culture is, however, of the essence of democracy, and while conferences such as those recently held by the British Association and the Association of Scientific Workers show how men of science have awakened to the social implications of their work and are increasingly ready to recognize their responsibilities as citizens, the challenge to fundamental thought about the institutions of government, untrammelled by party inhibitions or tradition, thrown down directly and by implication in these papers is one which they, no less than others, have yet to meet.

THE FRAGMENTATION OF SCIENCE

Mitosis

The Movements of Chromosomes in Cell Division. By Prof Franz Schrader. Pp x+110 (New York: Columbia University Press, London: Oxford University Press, 1944) 13s 6d net.

TWENTY years have passed since the appearance of Wilson's "Cell", that is of the third and all-embracing 1,200-page edition of this work. We may indeed take 1925 as the end of an epoch, the epoch of comprehensive description, always painstaking, usually thorough, and sometimes otiose, description. In the end this method collapsed of its own weight and broke into pieces. Since 1925 we have been busy putting the pieces together. There are many ways of doing this, most of them unprofitable, but some of them have given new structures of a kind not previously known in biology. Such, for example, is the genography based on the union of breeding analysis, X-ray breakage and salivary gland mapping. On the purely cytological side there is also the speculative structure based on a few simple observations of meiosis in polyploid plants, a structure on which we have been able to rest all our knowledge of genetic crossing-over as well as a large part of our knowledge of chromosome mechanics at meiosis and mitosis. Other special theoretical structures are arising, or will arise, from the new experimental methods of ultra-centrifuging, X-ray breakage, ultra-violet absorption spectroscopy, micro-incineration, specific enzyme treatments, and so on.

Such are the circumstances in which Prof Schrader, Wilson's successor, takes up his pen to continue the work. Prof Schrader, like his predecessor, is technically equipped for his task by a long and careful study of mitosis in certain Hemiptera. Theoretically he is equipped by his understanding of the change that has come over this field of research. He values highly the power of concentration in attack which the achievements of the last twenty years have

demonstrated. His theme is mitosis, the division of the cell and the nucleus. In treating it he has taken great pains in limiting his objective and avoiding side issues. He has relegated the resting, prophase and telophase nuclei to a chapter of notes at the end of the book. He has likewise excluded the peculiarities of meiosis from his argument, and the evidence from sex-chromosome behaviour, which he himself summarized in 1928, and which a less self-denying critic might have been tempted to consider is now grown too bulky or too awkward to take into account. The abnormalities of mitosis produced by cancer and by colchicine and X-ray treatments are sacrificed to the same economy. The uniformity of plants and the diversity of Protozoa (and here we may perhaps cavil) find no place. Genetics, chemistry and internal structure are all locked out or, one should say, thrown away, for they surely contain something of value for the study of mitosis.

After this generous clearance there is little left to distract us from the residue. This is simply the mitotic spindle and the centromere by which the chromosome is attached to this body, both of them stripped of their most significant variations. How does Prof Schrader deal with this residue? Old-fashioned writers, like Wilson, have faced the same problem. They have first said what happened in mitosis, how it varied in Nature and could be changed in experiment, and have then drawn the conclusion and expounded the theories that seemed to combine or clarify these conditions. Schrader's method, however, is a new one. Having established the 'reality' of the spindle fibres as a basic assumption in two pages, he goes straight to general theories. The inevitably *a priori* theories of forty, fifty and sixty years ago occupy most of his attention, but the young ones also get their turn until liquid crystals and tactoids are reached. Throughout the discussion observations and experiments appear only as the casual commentators, supporters or objectors, called in apparently to rectify the balance where some theory seems to be showing too badly or too well. For Prof Schrader is utterly impartial. If one theory is obviously useless it is admitted to have helped in its time, and if another theory is obviously sound it is degraded to a truism or a mere exaggerated fact.

With such a tale the end would be foreseen, even if the author had not stated it on the first as well as on the last page. It is that his inquiry after the perfect and ultimate theory has failed. Mitosis is still too complicated, and the assault still too diffuse, for success. He feels "confusion", "humility", "disillusion" and a "despair" tempered only by hope that still further concentration in the attack (or should he say, fragmentation in the objective?) may yet yield "definite promise of a final solution".

Prof Schrader's book may seem depressing, and especially to those who know the merit of his purely descriptive work. But it is not entirely without value. It contains the lesson that while specialization in technique and material is necessary and profitable specialization in theory, an arbitrary restriction of data, is a contradiction in itself. It is like mountain eering in manacles. That is why this book, on an immense subject, peters out into notes and trifle after seventy-five pages. In describing the past, and planning the future, of scientific theories we must consider all things before we choose to adopt or reject any of them, and in order to make that choice we must have a point of view, and perhaps even a theory, of our own. C. D. DARLINGTON

INDEXING THE HYDROCARBONS

Faraday's Encyclopedia of Hydrocarbon Compounds
Compiled by Dr Joseph Escott Faraday Vol 1
C₁ to C₆ Pp xxv+47+92+40+104+103 (Manchester · Chemindex, Ltd, 1945) £7 10s 0d

FOR many years past organic chemists have been making and describing in detail thousands of new organic compounds it was and is essential that a worker should know what had been done previously to his discoveries. The advent of Beilstein's handbook had a profound influence on progress when it appeared well over sixty years ago, for it enabled quick reference to the literature. Later it was supplemented by Richter, at first a private enterprise, but later taken over by the German Chemical Society, which created a considerable organization to keep it up to date. British chemical journals and *Chemical Abstracts*, like the corresponding American and German publications, have since contained a formula index on the Richter plan. Decennial indexes have been produced. Yet in spite of all, the magnitude of the task is so great that everything is decades out of date: the two long wars have contributed to the chaos. Now Dr Faraday will make a fresh start—less ambitious, because it confines itself to the hydrocarbons, and presented in loose-leaf form so that an annual issue of new sheets will keep it up to date either by inserting new pages or substituting new matter for old.

The choice of hydrocarbons is both indicated and happy, for they stand to-day in the forefront of chemical interest as bricks for further synthesis. It is sought to give for each both a wide range of physical properties and every known method of preparation.

The first volume deals with compounds containing from one to five atoms of carbon. Its price is £7 10s, which is reasonable in regard to present-day costs, but obviously restricts possession of the book to firms and university libraries. A larger sale than has been estimated would no doubt reduce the cost, and we are inclined to recommend that it be considered an obligation on the part of all firms who make use of hydrocarbons to possess a copy. The time saved by its use can be very considerable, and every chemical unit must carry its share of the burden of producing chemical literature. Up to now this burden has been very unequally distributed and has fallen on the shoulders of far too few loyalists concerned with chemical progress.

Reference to the book is quick and easy, the sheets relating to a particular compound are numbered in order, formula and alternative names are clearly given. Taking C₆H₁₀, trimethylethylene, as an example, eighty-one methods of preparation are given on six sheets, with references to the journal in which each of these is found. The nomenclature adopted naturally follows very closely the International Rules for naming Organic Compounds.

The Germans in the past have used their hold in scientific literature to propagate the doctrine of German supremacy in chemistry which it has proved so hard to destroy, not so much among chemists, who were aware of the falsity of the claim, as among the intelligent public and the financiers in the City of London, who would often accept an invention, however incomplete or spurious, brought them by a foreigner but would rarely listen to a British inventor. These pages of our credulity must be closed for ever, British inventions are best must be our slogan. We must produce and finance our own literature and not

be afraid to proclaim our own achievements. The secrecy imposed by the censorship to-day is a blight on progress, but it is small in comparison to that imposed by firms on their doings. How many know that the first magnesium from sea water was made in Britain and not in America? Surely this was a chance to tell the world of a British achievement.

In our opinion Dr Faraday has made a start on a project which deserves widespread support, if we fail him, then the chemical industry of Britain deserves to fail also.

E F ARMSTRONG

PLANT ROOT DISEASES

Root Disease Fungi

A Treatise on the Epidemiology of Soil-borne Disease in Crop Plants, and a First Exposition of the Principles of Root Disease Control. By S D Garrett (*Annales Cryptogamici et Phytopathologici*, incorporating *Annales Bryologici*, edited by Dr Frans Verdoorn, Vol. 1) Pp xiv+177 (Waltham, Mass Chronica Botanica Co., London Wm Dawson and Sons, Ltd, 1944) 4 50 dollars

TO the plant pathologist, at work on a root disease, there quickly comes a realization of the enormous complexity and essentially dynamic nature of his problem: the soil, its organisms, and their vagaries make a whole world. But it is a world susceptible to the methods of science, and already, in some instances at least, results based on exact observation and carefully controlled experiments have been obtained, in other instances, because of the incompleteness of experience and the insufficiency of precise data, the subject is at a more elementary stage.

As the sub-title indicates, the author has undertaken a not inconsiderable task. The many and varied aspects of root infection and of the spread of fungal pathogens in the soil have been faithfully dealt with, so, too, the effect of temperature, moisture content, texture, organic content and soil reaction upon parasitic activity are considered in detail and clearly set forth. The latter part of the book is devoted to the ascertained facts relating to the control of root-invading fungi. It may be noted that the author has not considered it within the scope of this volume to deal with the related problems of root physiology and ecology.

There can be no doubt that this work represents a close and fair review of the literature, which is extensive. As an up-to-date survey of work in a field in which he has special experience, Mr Garrett has written a book which should be of very considerable use to all engaged on the investigation of soil-borne diseases.

Due prominence has been given to the specific conceptions of this branch of botany. The author of a work such as this is necessarily limited by the contemporary state of knowledge. Because of the extensiveness of the subject and the relatively restricted number of workers engaged on it, much of the research, on the fungi of tropical soils for example, is still at an early stage of development. Generalizations based on existing knowledge must therefore be accepted with due caution.

Since the work aims at an exposition of principles, and since the subject-matter is by its nature somewhat discursive, brief summaries at suitable points would have added to the usefulness of the book by rendering it more incisive.

C W WARDLAW

RELATION OF CRYSTALLOGRAPHY TO CHEMISTRY

By DR. A. F. WELLS

Research Department, Imperial Chemical Industries Limited, Manchester

IN the development of chemistry two phases can be distinguished. First there is a subdivision into more or less self-contained sections, inorganic, organic and physical—a subdivision dictated by the increasing complexity of the subject. Corresponding divisions have taken place in the other natural sciences, and the training of scientific workers has become more and more specialized. In the second phase the gulfs between the different sciences and between the branches of a particular science tend to be bridged by theories and new techniques. For example, the foundations of modern chemistry were laid when physicists investigated the passage of electricity through gases and the emission of radiation from heated bodies, studies which eventually led to the modern theory of the structure of the atom. Just as the quantum theory contributed to the development of chemistry as well as physics, so within chemistry itself the techniques of the physicist and the physical chemist are required by the inorganic and organic chemist. Thus although the various branches of chemistry have separately become more complex, they have now much in common as regards theory and technique.

In relation to chemistry the science of crystallography occupies a special position. Classical crystallography was restricted to the study of the external forms of crystals and their physical properties, though the study of crystals naturally led to speculations concerning the fine structure of matter, with the result that much of the space-group theory required in X-ray crystallography was available long before it was possible to use it. With the discovery (by physicists) of the diffraction of X-rays by crystals the whole status of crystallography was altered. From being essentially a descriptive subject, of comparatively little importance to chemistry, it gave rise to a new technique making possible the determination of the spatial arrangement of atoms. Moreover, the new structural crystallography is not limited, as was classical crystallography, to the study of well-developed crystals, for its methods may be applied to powders, to quasi-crystalline materials in which there is only partial ordering of the atoms, and even to glasses and liquids. It has become customary to describe that part of the new knowledge which is of more chemical interest as 'crystal chemistry', while 'crystal physics' embraces the study of the physical properties of crystals and their relation to internal structure. In this article I shall endeavour to show that the subject-matter of crystal chemistry is of such fundamental importance to chemistry that it must be incorporated into chemistry as an integral part of that subject.

The question of the relation of crystallography to chemistry is not only of academic interest. It is intimately concerned with the practical problem of how chemistry should be taught, and the type of training determines the mental outlook of chemists and hence the way in which the subject develops. Certain practical advantages of a knowledge of crystallography are sufficiently evident, for example, the ability to recognize crystalline forms in microchemical

analysis and to identify solid compounds by means of their refractive indexes. The recent publication of a book on the optical properties of organic crystals is a sign of the increasing attention being paid to the use of crystallographic data for such purposes. We still await a systematic compilation of morphological data such as was envisaged many years ago by T. V. Barker. Indexes of optical, morphological and X-ray data represent three ways in which crystallography can be of immediate practical value to chemists. The ability to 'think in three dimensions' and the appreciation of the relative shapes and sizes of groups of atoms are invaluable to those designing molecules of particular shapes required, for example, in modern synthetic polymer research.

We might make two generalizations about chemistry which illustrate the artificiality of separating crystal chemistry from chemistry. The first is that the chemist is chiefly interested in reactions between atoms, ions or molecules of different kinds, and the second is that so far as structural studies are concerned he deals only with finite groups of atoms. These limitations arise from the very nature of chemical methods and illustrate two essential differences between chemical and physical methods of studying a substance. The chemist studies it by changing it into something else, that is, he investigates how it reacts with other substances, the nature of the products, the mechanism of the reaction, and so on. Furthermore, he can deal only with substances in the liquid, dissolved or gaseous states, in which they exist as finite molecules or complex ions. When, therefore, an indefinitely large grouping of atoms has been formed, it can be studied only by breaking it down into smaller fragments which can then be examined by these chemical methods. The physicist, on the other hand, studies the way in which matter interacts with energy in some form or other without, in general, causing any irreversible change in composition.

In certain cases the chemist is interested in the combination of atoms of the same element, for example, when they form a finite molecule (Cl_2 , P_4 , etc.), and the determinations of the numbers of atoms in these molecules were essential to the assignment of correct atomic and molecular weights. The cohesion of such molecules in the solid and liquid states involves only interactions of a feeble sort between the electronic systems of molecules within which the primary chemical valencies of the elements are already satisfied, that is, the crystal is built up of discrete molecules held together by van der Waals bonds. There are, however, other possibilities. For example, an element may form finite molecules in solution or in the vapour state, but further combination, by means of the same kind of bonds, takes place on crystallization, giving infinite arrays of atoms as in crystalline selenium (infinite chains) or black phosphorus (infinite layers). Some elements, indeed, have two crystalline modifications, one of which is built of finite molecules and the other of infinite 'molecules', as in the case of white and black phosphorus. In yet other cases there is no stable finite molecule, as with carbon and silicon. Not only similar atoms, but also similar molecules may join together to form more complex molecules. Where the latter are finite, the reaction comes within the province of chemistry, where infinite, the polymer is a solid. Thus molecules such as Fe_2Cl_6 and Al_2Cl_6 simply represent degrees of molecular complexity intermediate between the molecules AX_3

and the infinite 'molecules' in the solids. The formation of these intermediate molecules is the exception rather than the rule. As an example of another type of combination between similar molecules we may instance the dimeric forms of certain carboxylic acids. Here the two molecules are held together by hydrogen bonds of exactly the same type as hold together the molecules in the crystal. Just as there are two ways of building up an infinite array of molecules of oxalic acid by means of hydrogen bonds into infinite chains and layers in the two crystalline forms, so in other cases there may be two ways of uniting the molecules, to give on one hand a finite dimeric molecule and on the other the infinite array in the crystal. These examples should suffice to show that the comprehensive study of the interaction between atoms and molecules includes all cases of combination, whether the primary units be atoms or molecules of the same or of different kinds, and whether the product is a finite or an infinite grouping. We must now indicate other ways in which the study of the solid state has enlarged the scope of chemistry and contributed to our understanding of matters essentially chemical.

By enabling us to study atomic arrangement in the infinite arrays of atoms in crystals, X-ray crystallography has greatly extended the range of stereochemistry, a subject which hitherto had been restricted to the study of finite molecules and complex ions. We have already remarked that in order to study a substance by chemical methods it is necessary to use it in solution or in the vapour state, that is, to break down the extended groupings of atoms characteristic of the crystal into finite molecules or ions. Thus the information obtained from the study of the solid state is complementary to that provided by chemical methods, though the stereochemistry of finite molecules may also be studied—and with greater precision—in the crystal, for in molecular crystals the internal structure of the molecule is in general not appreciably affected by the relatively weak intermolecular forces. We may remark here that the physical methods have an important advantage, apart from their greater precision, over the chemical methods, in that they do not depend on deductions concerning the mechanisms of reactions, a complication inherent in the classical methods of studying stereochemistry. The study of crystals has had much less effect on organic than on inorganic chemistry, for a number of reasons. First, the structural units in crystals of the simpler organic compounds are generally the same finite molecules which are studied by the chemist. Second, most organic compounds are built from atoms of a small number of elements (carbon, nitrogen, oxygen, sulphur, hydrogen and the halogens), so that when the approximate disposition of bonds from these elements was known the rough configuration of quite complex molecules could be deduced. The third point is that relatively few complete crystal structure determinations of organic compounds have been made.

Inorganic chemistry, however, presents a very different picture. Not only have we to deal with a very large number of elements, but also there is the additional complication that many of them do not form molecules or complex ions amenable to study by the methods of classical stereochemistry, which required the preparation of molecules or complex ions exhibiting stereoisomerism or optical activity. Whereas, for example, the arrangement of bonds round a silicon atom had to be deduced from the

optical activity of a compound such as $(C_2H_5)_3(C_3H_7)_2Si(CH_2C_6H_5)(CH_2C_6H_4SO_3H)$, and whereas the evidence for a particular arrangement of bonds might be only the feeble optical activity of a single compound, the stereochemistry of an element is often established with certainty by the analysis of the crystal structure of a very simple compound or of the element itself. Thus the tetrahedral arrangement of the four bonds from a silicon atom is evident from the structure of the crystalline element, and the planar disposition of the four bonds formed by divalent palladium or platinum is proved by the crystal structures of the chloride ($PdCl_2$) and sulphide (PtS) respectively. Since detailed crystal structure determinations have been made of many more inorganic than organic compounds, the whole aspect of the structural side of inorganic chemistry has been changed.

The effect of studying the spatial arrangement of atoms in crystals has been much greater, however, than simply to extend the subject-matter of stereochemistry and to make its data more precise. The detailed study of bond-lengths and inter-bond angles, together with the similar information gained by the application of other physical methods such as spectroscopy and electron diffraction, has added greatly to our knowledge of the nature of the bonds between atoms. In the realm of inorganic chemistry the study of the solid state has given us knowledge of the constitutions of many large groups of compounds which could not be studied by purely chemical methods. Prior to the development of X-ray crystallography, it was not possible to elucidate the structures of such groups of compounds as hydrates, silicates, etc., which exist only in the solid state, and the postulation of whole series of fictitious silicic acids is perhaps the best-known example of the result of making deductions about the constitutions of solids without having any knowledge of the atomic arrangement therein. The knowledge we have acquired of the principles underlying the structures of compounds of many types enables us to appreciate the limitations of empirical formulae as means of expressing the constitutions of solids. For example, the compounds calcium carbonate ($CaCO_3$), silicate ($CaSiO_3$) and titanate ($CaTiO_3$) have quite different structures, the first containing discrete CO_3^{2-} ions, the second cyclic $Si_2O_7^{6-}$ ions, while the third contains no complex ions. The recognition that not only the satisfying of chemical valencies or the balancing of charges, but also geometrical factors play a part in determining the composition of a solid leads to a fuller understanding of concepts so fundamental to chemistry as the laws of chemical combination. If a substance, whether in the solid, liquid, or gaseous states, consists of stable finite molecules, then we expect to find the law of fixed proportions rigidly obeyed. Also, in the case of an ionic crystal such as sodium chloride ($NaCl$), the requirement of electrical neutrality necessitates the presence of equal numbers of sodium and chloride ions. Although non-stoichiometric crystals can be prepared by special methods (for example, by heating a crystal of sodium chloride in sodium vapour) the departures from stoichiometric composition are very small. In the case of ferrous sulphide (FeS), however, the sulphur lattice is sufficiently rigid to tolerate the absence of some of the iron atoms, with the result that the 'FeS' phase is stable over the range 50–55.5 atomic per cent sulphur, accounting for formulae ranging from $Fe_0.8S$ to $Fe_{1.1}S_{1.2}$ assigned to natural specimens of this

material. In this connexion it is interesting that ferrous sulphide is so often quoted in elementary text-books as an example of a chemical compound, and that it figured in the controversy between Proust and Berthollet over the law of fixed proportions. In 1804 Berthollet expressed the view that "the metals can combine with sulphur in very various proportions, and the combinations which are thus formed have very different properties according to their proportions. I am, in this case, again in opposition to the opinion of Proust, who asserts that by the invariable law of proportions sulphur and iron are fixed at 60/100". It would seem fortunate that these early investigators studied the system Fe-S rather than Ni-Te, for example, in which phases with all compositions ranging from NiTe to NiTe₃ are stable. Here, however, we are nearer alloys than chemical compounds; but this only serves to illustrate another point. No definite dividing line can be drawn between alloys and chemical compounds, and alloys—particularly the 'interstitial compounds' (certain hydrides, borides, carbides and nitrides)—are notable for their variable compositions.

So far we have been considering to what extent a knowledge of the arrangement of the atoms in the interior of crystals affects our outlook on chemistry. This knowledge is, however, also essential to an understanding of the properties of the surfaces of the crystal and of processes involving the formation or breakdown of the crystal. Reactions involving a solid phase must start at the surface of the solid, and such reactions are of particular interest both theoretically and practically. The oxidation of a solid metal was one of the first reactions studied quantitatively (the increase in weight of metallic tin on oxidation was recorded by Jean Rey in 1630), but the investigation of the mechanisms of such processes is difficult, and it is only recently that much progress has been made in this field. For example, the results of studying the dependence on oxygen pressure of the semi-conductivity of oxides such as cuprous oxide and zinc oxide, and of the rates of oxidation of the corresponding metals, suggest that these phenomena are closely related. In the case of the oxidation of ferrous oxide (FeO) through Fe₃O₄ to Fe₂O₃, we can now give some sort of physical picture of the process on the atomic scale. The activity of many surfaces is well known and is made use of in a variety of ways. The properties of a surface must be accounted for, not only in terms of the properties of the individual atoms or molecules composing the surface, but also of the atomic structure of the surface, that is, the actual arrangement of atoms in the surface and the difference between the environment of a surface atom and a similar one in the interior of the crystal. The phenomena of crystal growth—the development of different habits from different solvents, the effects of impurities on the habits of crystals and more generally of the form in which a solid separates from solution, whether crystalline or colloidal—all these are associated with the properties of atoms in surfaces and with the way in which the solute interacts with the solvent. The solubility of one substance in another is evidence of interaction between the two substances, and this may be of various kinds. For example, the interaction between molecules of naphthalene and benzene or between stannic iodide and carbon disulphide is quite different from that between, say, resorcinol and water.

The term 'soluble' is loosely used in various senses in chemistry, for example, when it is said that

sodium chloride is soluble in water, ferric chloride in pyridine, mercuric iodide in a solution of potassium iodide or finally a metal in an acid. Even when no obvious chemical reaction takes place, there may be important alterations in the constitution of the solution. Thus in solid ferric chloride there are infinite groupings of iron and chlorine atoms in which every iron atom is surrounded by six chlorine atoms. If this compound is dissolved in carbon disulphide, it forms molecules of Fe₂Cl₆, as it does in the vapour at temperatures below 750°C, but in solution in pyridine the condensation 2FeCl₃ → Fe₂Cl₆ is prevented by the linking of a pyridine molecule to each iron atom. Thus in these various cases we find that 'ferric chloride' exists in quite different forms with iron atoms bonded to 6, 4 and 3 chlorine atoms respectively.

There is much more to be known about a compound, therefore, than the mode of preparation and its chemical properties. It has a structural chemistry of its own if we include within the province of structural chemistry the relations between the constitution of a substance in different states of aggregation. Finally we may mention the interpretation of data concerning processes which involve the formation or breakdown of crystals. The analysis of data such as heats of fusion, sublimation and crystallization calls for knowledge of the actual processes taking place while the crystal melts, vaporizes or is built up, in terms of the nature and numbers of bonds broken or formed.

In conclusion, we would suggest that there is no longer any justification for drawing a dividing line between finite and infinite arrangements of atoms and regarding the study of the former as constituting chemistry and of the latter crystal chemistry. The chemist has concerned himself exclusively with finite groups of atoms because he must break down the infinite groups of atoms in crystals before he can apply his chemical methods to them. The tendency to regard all compounds as existing in the form of finite molecules arose quite naturally from the study of gases, which necessarily exist in this form, and from the intensive study of organic chemistry, which is concerned with substances existing for the most part as finite molecules in all states of aggregation. If the study of atomic arrangement in the solid state had become possible at an earlier stage, the scope of chemistry would not have been limited in the way we have been discussing. We have seen that as regards inorganic compounds, although it is true that some crystals may be broken down and reformed reversibly (for example, simple salts), while with others the breakdown of the crystal destroys the chemical identity of the compound (as in the case of silicates) yet in all cases there is a wealth of information which can be gained only by studying the infinite array of atoms which constitute the solid compound. Similarly, the fact that the molecules which exist in crystal of glycine may be studied in solution is no reason for neglecting to study the way in which they are held together in the solid state. In the attack on the structures of substances of increasing complexity, from the large finite molecules such as globule proteins and viruses to the infinite 'molecules' of fibres, natural and synthetic, the chemist must rely more and more on the crystallographer. When building up a chain step by step (for example, 2CH₃I + 2Na → C₂H₆ + 2NaI) the chemist could deduce the constitution of the product. When, however, he polymerizes simple aliphatic compounds to polymers of high molecular weight, for example, ethylene to

polythene, he can no longer determine the structures of his solid products and must rely on the X-ray crystallographer to tell him what he has made. The old chemical methods of synthesis and degradation give only limited information about the structural units, and to discover how they were originally linked together is not always within their power.

COMMENTS ON CHROMOSOME STRUCTURE

By DR. I. MANTON
University of Manchester

WHEN a great physicist takes the trouble to explain in simple language some of his matured thoughts on topics of general interest outside his own subject, it is an event for which one cannot be too grateful. The following remarks have been aroused by the appreciative perusal of Prof. E. Schroedinger's delightful little book "What is Life?"¹

Without attempting to summarize the whole of Prof. Schroedinger's argument, it is valuable to notice the great stress which is laid on the existence of two very different methods of obtaining orderly behaviour of matter in Nature. In the inanimate world 'order from disorder' is said to be the rule; the behaviour of matter in bulk being in most cases the expression of a statistical average of the behaviour of vast numbers of particles (atoms, molecules or the like) which, individually, may be doing the most diverse things under the sole compulsion of a tendency towards increased randomness. In biological systems, on the other hand, 'order from order' is met with. In such a system the most complex sequence of events may be determined and set in motion by the pattern of arrangement in space of a comparatively minute number of individual particles occupying relatively fixed positions with regard to one another. The paramount importance of the pattern of atomic arrangement in the particular case of the genetical material carried by the chromosomes is, in Prof. Schroedinger's view, the most interesting discovery of our time.

Few biologists will probably wish to dispute this in general terms. Cytological comment is, however, aroused by the details of its presentation from the circumstance that Prof. Schroedinger, at various points, is thinking in terms of certain assumptions regarding chromosome structure which are by no means universally held. It may therefore be of interest to inquire what change of view, if any, will be entailed if these assumptions are altered.

Prof. Schroedinger is much impressed by the singleness of the 'code script' in inheritance, by code script meaning the sum of hereditary material carried by a haploid nucleus (in genetical parlance this would be referred to as a genome). That only one chromosome set or genome is actually necessary for development is clearly shown by the existence of haploid organisms, for example, many of the lower plants, or cases of parthenogenesis in both plants and animals; it is therefore quite legitimate to ignore diploidy and polyploidy. Difficulties, however, appear at once if 'singleness' is interpreted literally in a molecular sense, and that this is Prof. Schroedinger's interpretation seems clear from his very interesting discussion of the size of a gene.

It might perhaps be questioned whether the 'size of a gene' is a desirable or legitimate use of words. In its original sense a 'gene' meant nothing more than the physical basis of an externally visible mutation, and if a mutation can be caused, as Prof. Schroedinger suggests, by a change of atomic arrangement, of the nature of a quantum jump, occurring within a molecule, then a gene, strictly speaking, is the changed part of that molecule and nothing else. It is an unfortunate biological practice which Prof. Schroedinger cannot be personally blamed for following, that the word is now often used in so many extended senses that it has little precise meaning left. In discussing the maximum size of a 'gene' from genetical data, the word denotes either the smallest piece of a chromosome which can have a genetically detectable effect, or the shortest distance between two mutations which can be separated by crossing-over; a numerical estimate of either of these by existing genetical or cytological methods may be expected to yield purely subjective values expressing present crudities of technique. In discussing the minimum size of a 'gene' as deduced from induction of mutations by ionizing radiations, the word is apparently equated with the range of influence of the minimum degree of ionization required to induce a mutation. The thing that Prof. Schroedinger really wishes to discuss is the fundamental molecular unit of chromosome structure, which is not necessarily identical with any of these concepts. The use of the word gene for this also may seem particularly unfortunate to a cytologist because some idea of structural discontinuity is almost inevitably implied. Mutations are discontinuous and arranged in linear sequence along a chromosome. Whether the fundamental genetical material in which the mutations occur is or is not also discontinuous (like beads on a string) is quite another question and one which neither cytology nor genetics can yet determine. This linguistic difficulty would perhaps best be met if the word gene were deleted from the vocabulary; one of the most pregnant of Prof. Schroedinger's sentences could then be paraphrased as—"We believe a mutation to be of the nature of a quantum jump and the fundamental unit of chromosome structure—or perhaps the whole chromosome fibre—to be an aperiodic solid".

At this point the sense in which the "whole chromosome fibre" can be regarded as a unit becomes of importance. There are at present two extreme views as to this, both supported by some positive evidence. According to the one which Prof. Schroedinger is using, the whole chromosome thread is a single structure at all times, except for a limited period during prophase when it is doubled in preparation for a nuclear division. The strongest piece of evidence in support of this is the differential behaviour of certain nuclear stages to irradiation by X-rays at dosages sufficient to cause gross chromosome fracture. Assuming that the statements in the literature are correct (for example, Riley 1936²) the position appears to be that in some organisms such as *Tradescantia*³, irradiation at prophase can cause fracture of half-chromosomes (chromatid breaks) but at other stages only breakage of whole chromosomes. In interpreting this as meaning that the chromosome thread is single at all stages other than prophase it is not always realized that this singleness could be conferred by spiral structure and is not necessarily based on singleness of the genetical material.

The spiral structure of chromosomes (or perhaps more correctly the helical structure, since the geo-

metrical figure involved would, in mathematics, be termed a helix) is probably not as widely known to scientific workers in general as its importance deserves and it is still far from being fully understood even by cytologists. That the apparent diameter of a fully developed chromosome is that of a helical coil has been known since 1880⁴ for meiotic chromosomes, though owing to technical difficulty the basic facts for mitotic chromosomes have only recently been elucidated. Examples of the structure, as revealed by special treatment or in rare instances spontaneously, are shown in Figs. 1-4 for the different sorts of division in the fern *Osmunda*. Fig. 1 shows an unpaired chromosome at the first meiotic division, with four large coils. At this stage all cytologists are agreed that the genetical material is double in preparation for the second meiotic division and that in a paired chromosome genetical crossing-over between chromatids (half-chromosomes) has taken place; both chromatids, however, share a common spiral path. At

single spiral in certain of the chromosomes is perhaps also an after-effect of the irradiation, but it accords very fully with the other evidence.

The other extreme view of chromosome structure, which is becoming increasingly accepted in the U.S.S.R. and the U.S.A. and (before the War) in Japan, though in Great Britain it has been somewhat opposed, is that a chromosome is fundamentally many-stranded at all stages. If the physical basis of unitary behaviour of chromosome or chromatid can in part at least be interpreted in terms of helical structure rather than molecular structure then perhaps the chief objection to this view has been removed. An example of the type of observational evidence on which the view is based is contained in Fig. 5⁶. The specimen here is at a later stage¹ of anaphase than that of Fig. 4 and had not been subjected to X-rays. Instead it had been given the normal pretreatment with ammoniated alcohol which is generally necessary to make the spiral appear.

Fig. 1. Unpaired chromosome of *Osmunda* at the first meiotic division after ammonia treatment for spiral structure. Acetocarmine preparation photographed in clove oil by visual light. ($\times 2000$.)

Fig. 2. Split chromosome at the second meiotic division in *Osmunda* after ammonia treatment for spiral structure, the two chromatids are attached only at the centromere (c). Acetocarmine preparation, ultra-violet photograph. ($\times 2000$.)

Fig. 3. Split chromosome at metaphase of the third spore division in *Osmunda* showing spiral structure without special treatment. Acetocarmine preparation, ultra-violet photograph ($\times 4000$) negative print (the positive of this and others in Manton and Smiles, 1943⁴).

Fig. 4. Anaphase of the first spore division in *Osmunda* fixed 30 hours after irradiation of the uninucleate spore with X-rays at 2,500 r.* showing fractures, fusions and abnormally clear spiral structure. Acetocarmine preparation, visual light photograph. ($\times 1000$.)

Fig. 5. Anaphase of the third spore division in *Todea* after ammonia treatment. showing lateral separation of component strands. Acetocarmine preparation, ultra-violet photograph ($\times 4000$), negative print (the positive of this and other chromosomes in Manton, 1945⁶).

the second meiotic division, Fig. 2, the two chromatids diverge so widely that they are only in contact at the region known as the centromere (marked c in the figure). A new spiral, differing in diameter and in number of coils from that at the previous division, affects each chromatid. At a somatic division, Fig. 3, the number of coils is increased still further but the two chromatids lie close together. It is, however, certain that the spiral in each has been independently formed for, in the case figured, direction of coiling was determined in corresponding parts of the sister chromatids and found to be opposite⁵. There must therefore be two separate spirals during prophase and it is possibly this which is detected by the X-ray breakages. At anaphase one of the two spirals passes to each pole, and that the helical coil at anaphase is indeed single seems to follow from the unusually clear case of Fig. 4. This differs from the preceding in that it had been subjected to X-rays some hours previously and many types of fusion and fracture are displayed. The unusual clarity of the undoubtedly

The plant concerned is, however, not *Osmunda* but the closely related fern *Todea*, and the pretreatment and method of mounting acting together have in this case produced a remarkable lateral separation of longitudinally running strands. No less than four strands per chromosome are unmistakably present, most clearly countable, in the original print, in the left-most chromosome. With the detection of quarter-chromosomes the limit of optical resolution has been reached, even with light of short wave-length; but it is by no means impossible that further subdivision would be found to be present if resolution could be extended.

It is not easy to determine the diameter of an object near the limit of visibility, but the fact that quarter-chromosomes are visible at all suggests that their thickness is likely to be of the same order as the wave-length of the light used (275 $\mu\mu$). In round numbers and for the sake of argument this may be put as approximately 3000 A. Now if Prof. Schroedinger's figures for the 'size of a gene' be utilized,

ome simple arithmetic will provide a rough estimate of the possible limits of many-strandedness assuming his to exist. The higher limit for the 'size of a gene' is given as 300 A and there would therefore be room in a quarter chromosome of *Todea* for some 75 threads of this width. The lower limit of size is given as 'ten atomic distances cubed' which, for a protein molecule, might perhaps be put as of the order of 50 A. cubed. There is room in a quarter chromosome of *Todea* for nearly three thousand threads of diameter 50 A. The real unit of chromosome structure is likely to lie in between these two extremes and it is probable that allowance must also be made for some empty spaces between the strands. Nevertheless the figures, rough as they are, indicate at least the possibility that in a whole chromosome, not one but between 300 and 2,000 duplicate versions of the genetical material may be present.

This is not quite the same as the unique phenomenon visualized by Prof. Schroedinger, though it is no doubt sufficiently close to it still to come under the general heading of 'order from order' rather than 'order from disorder'. The importance attributed to atomic arrangement in the 'aperiodic solid' of the unit fibre is almost certainly correct, and this property is shared by many other protoplasmic structures besides the chromosomes, notably by enzymes. If the view of chromosome structure put forward above be correct, however, a chromosome may be found to owe some of its peculiar powers not to the aperiodic fibre as such but to the fact that bundles of these are co-ordinated together in a manner recalling, though not necessarily exactly resembling, the periodic crystals. The 'whole chromosome fibre' may in fact have to be visualized as an aperiodic solid in its longitudinal dimension but as periodic in its transverse dimension.

The recognition of an element of periodic structure in one dimension of the genetical material would perhaps be a minor emendation in the general philosophic view of a chromosome. The issues raised here, however, of immediate importance in cytology, and I trust that Prof. Schroedinger will forgive me. I have used his very interesting little book as an occasion for directing attention to them.

ALESSANDRO VOLTA, 1745-1827

By ENG.-CAPT. EDGAR C. SMITH, O.B.E.

TO few men of science has more homage been paid than to the Italian physicist Alessandro Volta. In his life-time he was received into the highest scientific circles, and the centenary of his most important discovery and the centenary of his birth were the occasions of great international gatherings in the land of his birth. Since then, through the munificence of Signor Somani, Como, here Volta was born and where he died, has been enriched with a beautiful Volta Temple, a finely designed circular hall surmounted by a dome. This interesting building stands in the public gardens near

the edge of a lake in Como, from which can be seen the waters, the fields and woods and the mountains amidst which Volta grew up, a student and a sportsman. For centuries the family from which he sprang had been associated with the district, and its coat-of-arms consisted of a vault (in Italian, *volta*) of a silver gate on a blue background.

Volta was born on February 18, two hundred years ago, being the son of Philip and Madeleine, descendants of the family of the Counts Inzaghi. Well educated under the supervision of an uncle, Volta began experimenting in electricity as a youth, and electricity remained his one and only love. Thanks to the invention of friction electric machines and the Leyden jar, and to Franklin's epoch-making discoveries, there were scores of devotees to the study of electricity, and during the eighteenth century thousands of new experiments were performed and a mass of observations full of promise was accumulated. In the last year of the century, it fell to Volta to make one of the most fruitful inventions in the history of science. As a young man, he corresponded with such able experimenters as Giovanni Battista Beccaria (1716-81) and the Abbé Nollet (1700-70), and in 1769, at the age of twenty-four, published his first paper. In 1774 he became superintendent of schools in Como, in 1776 professor of physics there, and in 1778 professor of experimental physics in the University of Pavia, which remained his headquarters for the rest of his active career. Those early years had been marked by the invention of his electrophorus, and the suggestion of a method of long-distance signalling by electricity. But more important in his own development were his travels, during which he made a host of friends and acquaintances, and, especially in Great Britain, became familiar with the leaders in scientific thought. In 1777 his journeys took him to Germany and Switzerland, during which he met a kindred spirit in de Saussure, in 1781 he went as far afield as Belgium, Holland, France and England, and in 1782 he was in England again, and then went to Austria. In England he admired the pavements of London, the steam engines in Shropshire, and the mills at Manchester, at Portsmouth he visited the fleet under Admiral Howe. He became known to Franklin, Watt, Priestley, Laplace, Lavoisier, Van Marum and many other famous leaders in science.

Living in London at that time was Volta's countryman Tiberias Cavallo, who had come here to follow a commercial career but had succumbed to the fascination of sparks and discharges, and had published "A Complete Treatise of Electricity". To Cavallo, Volta in 1793 addressed two letters which appeared in the *Philosophical Transactions* under the heading "Account of Some Discoveries made by Mr Galvani of Bologna, with Experiments and Observations on Them". Behind this title lay a long series of trials with metals and the nerves of not only frogs, but also of quadrupeds, birds, fishes, reptiles and amphibia. Desiring to experiment on the human body, he used a piece of tinfoil and a silver spoon separated by his tongue, thus introducing an experiment which untold numbers have repeated.

In 1791 he had been made a foreign member of the Royal Society, and the Society now proceeded to honour him with the Copley Medal, Sir Joseph Banks in his address remarking, "The experiments of Professor Galvani, until commented upon by Professor Volta, had too much astonished, and perhaps, in some degree, perplexed many of the learned in various parts

of Europe To Professor Volta was reserved the merit of bringing his countryman's experiments to the test of sound reasoning and accurate investigation. . . . Just at that time Europe was in the early throes of one of her periodical upheavals, and it was partly this which had led Volta to send his memoir to London.

Seven years later came a much more important paper in the form of a letter of 8,500 words in French to Sir Joseph Banks, which ultimately appeared in the *Philosophical Transactions* under the title "On the Electricity Exeited by the Mere Contact of Conducting Substances of Different Kinds". The effect of this communication was as startling as the announcement of Rontgen's discovery of fifty years ago. The whole scientific world became agog with galvanic piles, batteries, 'crowns of cups' and so forth. For the first time electricity could be obtained in steady and continuous currents, and so was marked an era in electrical science. The fellows of the Royal Society having been enlightened, the members of the Royal Institution, just founded, of course had to be told, but unfortunately Dr Garnett, not long engaged as "lecturer and scientific secretary and Editor of the Journals", made a slip and ascribed the invention of the pile to the French, Rumford heard of this, and on May 29, 1800, wrote to Banks "I knew nothing of the matter until it was too late to prevent a mistake. I have, however, insisted on its being rectified as far as it is possible in some future lecture." Next day he wrote again that Dr Garnett is perfectly ready to atone for his lapse and will make this declaration. "Having by mistake on Wednesday, in the course of my public lecture, ascribed to the French philosophers a new and important discovery relative to galvanism, which on inquiry I find belongs to Professor Volta of Milan, I feel it my duty

The old records are eloquent of the enthusiasm about the new apparatus, and fifty years later J. D. Forbes wrote "The invention of the pile may in many respects be placed on a par with that of the steam engine. The results of the former were indeed more interesting immediately to pure science, the latter to the arts of life and the needs of civilization. Yet after half a century, this distinction can hardly be drawn with severity. The rapid pace of steam is insufficient for our needs. The electric wire conveys to its destination, ere the locomotive has time to start on its journey, tidings of joy and sorrow—life and death—of victories won, and kingdoms lost."

In the last year of the dying century, Volta was at the height of his career, a conqueror of Nature. In his native land was another conqueror, Napoleon, who in June won the battle of Marengo and so became master of northern Italy. Next year the two met in Paris. On November 11, 1801, Count Rumford wrote to Sir Joseph Banks, "At the last meeting of the mathematical and physical class [of the National Institute] the First Consul came in.

He stayed about an hour—till the meeting was over. Volta read a paper on Galvanism and explained his theory of the action of the voltaic pile or battery.

After Volta had finished his memoir the First Consul demanded leave from the President to speak, which being granted, he proposed to the meeting to reward M. Volta with a gold medal, and to appoint a committee to confer with M. Volta on the subject of his experiments and investigations respecting galvanism and to make such new experiments as may bid fair to lead to further discoveries. He delivered his sentiments with great perspicacity and

displayed a degree of eloquence which surprised me." Volta eventually got his medal and also a sum of money, and was elected a member of the Institute. Later, he became a senator of the Kingdom of Lombardy and a Count, but the world of science was enriched by no more discoveries by him.

Volta continued to work quietly at Pavia until 1819, when after acting as director of the Philosophical Faculty of the University for four years he retired to his beloved Como, where he died on March 5, 1827, at the age of eighty-two. Up to the age of forty-nine he had remained a bachelor, then he married Teresa Pellegrini, by whom he had three sons. His grave and monument are at Como, where at the great Exhibition held in honour of his memoir in 1899 a fire destroyed a great deal of his original apparatus.

One of the best recent accounts of Volta and his work is contained in illustrated articles by Mr. Frank Walker in *Engineering* of January 1938.

CORROSION OF METALS IN SOIL

THE corrosion of metals buried underground is a problem of very considerable importance, it is one also of great complexity. In 1922 experiments were initiated by the U.S. National Bureau of Standards to determine the effects of various soils on materials in general use for pipes buried in the ground. From time to time reports have been issued summarizing the results obtained as the work progressed, a report has now appeared dealing with an investigation begun in 1932 to study the corrosion resistance of both ferrous and non-ferrous materials and the effect of applying improved protective coatings*.

No attempt was made to obtain series of specimens differing step-wise from each other. Manufacturers were invited to submit specimens which they believed or hoped would be resistant. Hence the various samples differed in so many ways that co-ordination of the results is a matter of extreme difficulty. The authors have themselves realized this, and deal with their data in a thoroughly sound and logical manner. They give warning that the results must be interpreted with care partly in consequence of the difficulty of obtaining satisfactory 'repeat' results, and also because the experimental conditions were not identical with those to which pipes would probably be subjected in practice. This latter point is particularly true when protective coatings are applied because small laboratory specimens can be more carefully coated and handled with greater care than is possible in practice. As a result, when the attempt to arrive at a general conclusion of importance, it is so whittled down with exceptions and provisos as to be of disappointingly limited value. Although the detailed results will be of great value to the manufacturers who supplied the materials, upon whose behalf the research was, of course, mainly carried out, it is obviously the general conclusions that will appeal most to European readers.

Fifteen different soils were chosen, including several clays and loams, peat, muck and cinder

* Soil-Corrosion Studies, 1941. Ferrous and Non-Ferrous Corrosion Resistant Materials and Non-bituminous Coatings. By Kirk H. Loj and Melvin Romanoff. *Journal of Research, Nat. Bur. Stand.*, No. 5 (1944).

important factors mentioned are the texture of the soils, their retentiveness of water, pH values and water-soluble contents. The pH values of the soils chosen ranged from 2.6 in Rifle peat to 9.4 in Merced loam, thus covering the ambit of soils in general.

The reasons why pipes in some soils corrode more rapidly than in others have not as yet been fully determined. Soil solutions are often too weak to account directly for the observed corrosion, but the electric conductivity of soils containing soluble salts is important. Soil bacteria may also play a part. Differences of potential between various points on the surface of the material are a fruitful source of trouble, these may be due to many causes, including the presence of scale, segregations and variations in the soil itself in contact with the material in different places.

Eight cast irons were tested, including one high-alloy cast iron with 2.61 per cent chromium and 5.0 per cent nickel. The results of exposures for two, five, seven and nine years are compared, and the superiority of the high-alloy metal demonstrated both as regards loss in weight and depth of pitting. The plain and low-alloy cast irons (c. 0.5 per cent copper) with silicon ranging from 0.95 to 2.50 per cent behaved very much alike.

An interesting experiment consisted in embedding two different plain cast irons in contact in very wet loess clay, the water-soluble material of which was almost entirely sodium chloride. At first one of the cast irons was cathodic to the other, but after considerable drying of the soil a reversal took place, the anodic metal now becoming anodic. This illustrates the importance of such factors as soil aeration and water-retentiveness, as also the difficulty of forecasting results in practice in view of seasonal variations in rainfall and drought.

For many years attempts have been made to increase the resistance of steel to corrosion by alloying with different elements such as chromium, nickel and copper. In the present research, cleaned 5 per cent chromium steel, after various periods of exposure up to nine years in ten different soils, lost less in weight than ordinary steel but was more deeply pitted. Many investigators have already directed attention to this behaviour of chromium steels under quite other conditions of corrosion. The authors attribute it to formation of a protective superficial oxide film which breaks down locally, setting up potential differences leading to localized corrosion. This is a generally accepted view. On the other hand, cleaned nickel-copper steel (2.47 per cent nickel, 1.08 per cent copper) proved superior to ordinary steel both as judged by loss in weight and depth of pitting, whereas the same steels exposed with adherent scale showed no advantage after four years.

Turning now to the non-ferrous metals, a useful table is given summarizing the losses in weight sustained by nine copper alloys relatively to that of rough pitch copper taken as 100. This latter metal was very resistant to corrosion, as was also red brass (14.8 per cent zinc) and copper-nickel alloy (5 per cent zinc, 20.0 per cent nickel). The zinc content of the brasses included in this set ranged from 4.8 to 39.6 per cent (Muntz metal), and the apparent losses in weight rose steadily with the zinc content. It is pointed out, however, that in some cases the observed losses do not accurately indicate the extent of corrosion, since part of the zinc had been removed by selective corrosion which weakened the material. The observed depth of pitting also

might be misleading as in some soils dezincification occurred, the depth of which was not known. The addition of 0.08 per cent arsenic to Muntz metal did not prevent dezincification, but the authors suggest that more arsenic might yield better results.

It was noted that, in general, soils that are severely corrosive to iron may be non-corrosive to lead, the exceptions being highly organic soils. This is attributed in part to the formation on the metal surface of insoluble salts, such as sulphate, chloride or carbonate, which protect the underlying metal from attack. Organic salts, on the other hand, are usually soluble. The addition of 5 per cent antimony did not materially improve the resistance of the lead.

Copper tubes coated with a thin layer of tin appeared to receive a temporary protection, but in the course of four years much of the tin disappeared. Reversal of potential is suggested as a cause of failure, the tin being anodic and protecting the copper just as zinc protects galvanized iron. But reversal might be caused by the presence of tin-copper alloys which are cathodic.

Experiments with lead-coated steel pipes were not encouraging, the authors doubt if a lead coat of any reasonable thickness can be satisfactory in corrosive soils. On the other hand, zinc applied by the hot-dip method to the extent of some 3 oz per sq ft increased resistance to corrosion, it is concluded, however, that it would not add more than four years to the life of the pipe.

Vitreous enamel, rubber coatings, a thick moulded coating of China wood oil with mica, and a baked-on 'Bakelite' coating were each found to reduce corrosion substantially over periods of from four to nine years.

It is impossible in a brief article to do full justice to the mass of data contained in the report. The foregoing is an attempt to lay before the reader the salient features of the research.

J. NEWTON FRIEND.

OBITUARY

President Roosevelt

NOT since Abraham Lincoln was assassinated at the moment of victory eighty years ago has the death of an American president shocked the world like the passing of Franklin Delano Roosevelt on April 12, at the age of sixty-three.

Over the success and achievements of the New Deal policy which Mr. Roosevelt initiated when he entered on his first term of office as president in 1933 there is still much controversy. The policy had its faults, but, comprising economies in the public service, plans for unemployment relief, public works enterprise on a large scale, and schemes for the rehabilitation of agriculture, with the accompanying National Industrial Recovery Act, which authorized the President to frame a code of regulations for each industry, and the further legislation passed during 1934 and the first part of 1935 dealing with currency, tariff, public utilities and taxation questions, and the Social Security Act in which, for the first time, the United States accepted the principle of national unemployment insurance and old-age pensions, it nevertheless was a landmark in American history.

The full extent of Mr. Roosevelt's contribution to the New Deal policy cannot perhaps be accurately assessed as yet, though the bitterness of the personal attacks on the President made by its opponents and the determination with which he himself supported

it in the face of the judgment of the Supreme Court in May 1935 invalidating the Industrial Recovery Act and later decisions which similarly declared unconstitutional several minor but important features of the New Deal indicate that the policy owed much to the impress of his forward-looking mind. Already in the achievements of the Tennessee Valley Authority that outlook has been vindicated, and the possibility of a new and more positive conception of government demonstrated to the world. That experiment was not only a social venture but also, in a true sense, a scientific approach to the problem of the conservation and development of national resources, and the integration of local and regional administration with central government. It is an approach of exactly the same order as that which characterizes the report of the Committee on Administrative Management with which Mr. Roosevelt's name is also associated. That great State paper and the Tennessee Valley Authority are sufficient evidence of Mr. Roosevelt's appreciation of the importance of a scientific approach to the problems of government and planning, and when the dust of controversy settles down, it may well be found that scientific workers have a special reason to hold Mr. Roosevelt's name in remembrance for the way in which his determination and vision made possible a more effective contribution of science to the service of mankind, while at the same time his sense of human values never allowed that contribution to be overstressed.

While his well-known physical disability may well have increased Roosevelt's sympathy for and understanding of the less privileged people of his country, his forward-looking mind led him to seek further ways of overcoming it. In his 'fireside talks' he utilized the new technique of broadcasting with skill and success and was able not only to overcome the obstruction of Congress to measures which he regarded as essential and urgent but also to win a place in the mind of the ordinary citizen of all lands as the moral champion of freedom and human rights against tyranny and aggression. He was one of the earliest, even amid his preoccupation with the New Deal, to sense and give expression to the seriousness of that challenge to liberty, and the skill with which he used his broadcasting technique and endeavoured to express rather than lead public opinion during the first few months of the War was an important factor in securing endorsement of such successive acts in support of Great Britain and the cause for which the United Nations now stand as the setting up of a permanent joint board to consider plans for the defence of the United States and Canada, the transfer of over-age American destroyers to the Royal Navy and the lease of naval and air bases in British North America to the United States, and his great personal triumph in re-election for a third time in November 1940.

In the following year down to the Japanese attack on Pearl Harbour, Mr. Roosevelt's genius for timing was even more strikingly manifested, and the British people, and indeed the United Nations, can never forget the consummate skill with which he handled such matters as Lend-Lease, the establishment of air bases in Greenland, the dispatch of American forces to Iceland, and the amendment of the Neutrality Act. Much, no doubt, was due to the skill with which the President in his broadcast addresses and speeches voiced the aspirations of the common man and showed the way in which his policy tended to satisfy them. Even before the Atlantic Charter was drafted,

Mr. Roosevelt had showed a gift for the right and effective phrase which put some of his speeches, like those on the four freedoms and on the arsenal of democracy, alongside the Gettysburg speech of Lincoln in the literature of democracy.

On Roosevelt as a war leader the time for judgment has not yet come. Imagination has seized or the way in which this crippled leader has flown across the world to attend one conference after another. Within these years, moreover, he saw the establishment not merely of such joint agencies as the Anglo-American Combined Raw Materials Board and the corresponding Food Board, the Middle East Supply Centre, the Anglo-American Caribbean Commission, the post-war implications of which the President was one of the first to see, but also the inauguration of such definite organizations to deal with post-war problems as U.N.R.R.A. and the Food and Agricultural Organization.

It was these perhaps and the tentative scheme worked out at Dumbarton Oaks, considered further at Yalta, and now to be discussed at the San Francisco Conference that lay nearest his heart. While he did not live to see the moment of complete victory, he lived long enough to see it close at hand and to know that so far as such victory, complete, comparatively cheap, and dramatic could justify his choice of commanders, his judgment and courage have been fully vindicated. But if Mr. Roosevelt was an organizer of victory it is as one of the great architects of human liberty that he will be best remembered. We cannot measure yet what his passing may mean in inspiration and authority just as the foundations of the new world order he has done so much to plan are to be laid. Among the makers of America he will rank with Washington, Jefferson, Jackson, Lincoln and Wilson. But more almost than any of his predecessors he had the confidence of the common man, and the common man, looking back, while endorsing the verdict of the man of science that he gave science a wider opportunity to serve mankind, may well come to regard him above all as the architect of a world order in which the four freedoms are at last enshrined. Roosevelt himself would ask no more of his countrymen or of the United Nations than that they should continue to accomplish thoroughly this task to which he—and they—have set their hands. Gratitude to Britain's friend in her finest and darkest hour demands no less. "We have learnt," said Mr. Roosevelt in his Fourth Inaugural, "that we cannot live alone, at peace, that our own well-being is dependent on the well-being of other nations—far away. We have learnt to be citizens of the world, members of the human community." His infinite patience and tact and the inexorable march of events have committed the people of the United States overwhelmingly to joining some form of world organization. In a true sense he has given the world the tools and the opportunity to build again. There can be no more fitting tribute to his memory than to finish the job and to secure that the structure is adequate to the purpose to which it is dedicated.

But no tribute to President Roosevelt would be complete without reference to the help he received throughout his career from his wife, whom he married in 1905, Anna Eleanor Roosevelt, a niece of Theodore Roosevelt. To her and her four sons and daughter will be extended the heartfelt sympathy of the British people, many of whom have reason to know how nobly Mrs. Roosevelt seconded the President's efforts to aid them when they stood almost alone.

NEWS and VIEWS

Forest Products Research Laboratory

Mr W. A. Robertson

MR. W. A. ROBERTSON retired on March 31 from the position of director of forest products research (Department of Scientific and Industrial Research). He took over charge of the Laboratory at Princes Risborough in 1933, the earlier part of his career having been spent in the Indian Forest Service, mainly in Burma. Mr Robertson has thus been responsible for the direction of timber research in Great Britain during a period of important development which would undoubtedly have been greater but for the restrictions caused by the War. In 1941, when the Secretary of State for the Colonies decided to appoint a forest adviser, Mr Robertson was selected for this responsible post on a part-time basis. He will now be enabled to devote his entire attention to the problems confronting the Colonial Office in its reorganization of the Colonial Forest Service. In view of his wide experience, it may be considered fortunate that Mr Robertson's services will continue to be available in this capacity.

Dr. F. Y. Henderson

DR. F. Y. HENDERSON, who has taken up the post of director of forest products research on Mr Robertson's retirement, joined the staff of the Imperial College of Science and Technology in 1921 as plant physiologist. He devoted much of his time to research, and took an active part in teaching, and organizing the practical teaching in plant physiology. He was also for many years director of biological studies at the John Cass Institute, and superintendent of examinations for the Pharmaceutical Society of Great Britain. In 1931 Dr Henderson took over the work of Prof Percy Groom as timber technologist, and did much teaching in this field as well as research on the biological changes in felled timber.

Research in Animal Health at Aberystwyth

THE research professorship in animal health endowed by the generosity of Lord Milford at University College of Wales, Aberystwyth, has been filled by the appointment of Mr Alastair N. Worden. Mr Worden, who is twenty-eight, was educated at Queen Elizabeth's School, Barnet, the Royal Veterinary College, London, and St John's College, Cambridge. After experience of veterinary practice for more than two years with Mr J. Pickup, of Barnet, Mr Worden was awarded in 1938 a Ministry of Agriculture studentship in animal health, spending the first year of his tenure of this studentship in the Division of Nutrition of the Lister Institute, the second in the Bacteriological and Biochemical Departments of the Ministry of Agriculture's Veterinary Laboratory at Weybridge and the third in the Department of Agriculture at the University of Cambridge. He also spent some time at the Rowett Research Institute, Aberdeen. In 1941 he was appointed to the Biochemical Department of the Institute of Animal Pathology, University of Cambridge. His research has dealt mainly with human and animal nutrition and with the relation of nutrition to infectious diseases. He is a member of the Parliamentary and Scientific Committee on which he represents the Universities Federation for Animal Welfare and he is secretary of the Institute of Animal Behaviour.

Prof Worden starts with the great assets of youth, energy and the breadth of outlook which his training has given him. He goes to a centre already made famous by the work done by Sir George Stapledon and Dr T. J. Jenkin at the Welsh Plant Breeding Station at University College, Aberystwyth. Everyone will wish him success in a field which has become, as one result of the War, of great moment, not only to Britain, but also to the world in general.

Educating the Citizen

THE central problem of the planned society is, as Prof. H. J. Laski has pointed out, to make the issues at stake intelligible and to bring out in individuals the interest that compels action, in 'Planning Our Country', J. F. Adburgham and Elizabeth Halton well maintain the standard set by earlier pamphlets in this 'Unless We Plan Now' Series (English Univ Press, Ltd 4d net). The main aspects of the problems involved in town and country planning are simply but adequately explained and in a way which should conduce to discussion. There is a short but adequate bibliography, and the pamphlet should fulfil its avowed purpose of bringing home to the ordinary citizen the exact meaning of planning and of how much depends on his contribution and interest if effect is to be given to such proposals as are to be found in the Barlow, Uthwatt and Scott reports.

Much the same can be said of the pamphlet 'The Struggle for Democracy', by W. E. Brown, in the 'Changing Britain' Series (Univ of London Press 1s net). This is even more elementary, and the appeal is largely pictorial. The graphic presentation shows vividly how the development of the British system of government reflects the efforts and strivings of the individuals in the community. The pamphlet indicates not merely how immense has been the broadening of the basis of government and of the sphere of government action in the last century, but also, and more important still, that government is not to be thought of as something apart from the ordinary citizen: it is a matter of 'we', not of 'they', and the interest or inertia of the ordinary citizen, what he does, as well as how he votes, that ultimately shapes our institutions.

Rose-bay Willow-herb and Honey Bees

In the *Bee World* of January, A. Norman Handley discusses the status of the rose-bay willow-herb (*Epilobium angustifolium*). He mentions that the Press has joined forces with the farmers in condemning this plant as a noxious weed. The author believes that it is very questionable whether the plant could establish itself in properly cultivated ground. The roots appear to thrive best on waste lands where the soil is firm and undisturbed. The beekeeper, however, appreciates this herb because it yields valuable nectar and pollen especially during periods of scarcity from about early July until mid-August. In 1944, which was a notoriously bad year for bees, many hives managed to build up and even store surplus nectar from the rose-bay willow-herb. This plant also provides humble bees with food at a time when the next year's queens are being reared. The value of these insects as a general aid in pollination and a particular help in the case of red clover is, of course, well known. Now that the author has brought up this subject it would appear desirable that the true status of this kind of willow-herb should be determined. Much more information is needed before it

will be possible to account for the sudden appearance of the plant in land that has been ploughed or cleared and whether it is due to buried seeds or to other causes

Mme Lepaute : an Eighteenth Century Computer

ELIZABETH CONNOR, Mount Wilson Observatory, Carnegie Institution of Washington, has written (Leaf 189, Astro Soc Pac, Nov 1944) a short account of the astronomical work of Mme Lepaute, whom Lalande considered "the only woman in France who had genuine knowledge of astronomy". As a child she was a voracious reader, and it was generally recognized by those who met her that she had a brilliant mind. When Lalande and Lepaute, to whom Mme Lepaute (*née* Nicole-Reine Étable de la Brière) was married in 1748, collaborated in a treatise on clock-making, Mme Lepaute calculated a table for the book containing a number of oscillations for pendulums of different lengths and the lengths of pendulums corresponding to a given number of vibrations. Her great work was the assistance that she rendered in the computations of the perturbations of Halley's Comet, and Lalande pays her a tribute when he affirms that without her help Clairaut and he would scarcely have undertaken this enormous task. In 1759, Lalande was placed in charge of the *Connaissance des Temps*, and Mme Lepaute became one of his assistants. When this work was given to someone else in 1774, they concentrated their attention on volume 7 of the "Ephémérides", and Mme Lepaute made all the calculations for the sun, moon and planets for both volumes 7 and 8, covering the period 1774-93. In addition to this, she devoted much time to eclipses, computing a table of parallactic angles which was useful in eclipse work. She also made computations for the observation of the transit of Venus in 1761, and wrote a memoir on the subject for the Academy at Béziers. For twenty-five years she was engaged continuously in astronomical work, but her eyesight was finally affected and during the last years of her life she was unable to apply herself closely to the subject.

A 1,000-g Centrifuge

IN CONNEXION with recent development work, the Bell Laboratories have designed a centrifuge for the purpose of subjecting objects to high accelerations under conditions permitting the effects of the acceleration to be studied. The machine is described and illustrated by R. M. Pease in an article in the *Bell Laboratories Record* (22, No 16, Dec 1944). Machines of this general type have been built before, but there was none available that would develop high enough accelerations. For the required tests, an acceleration 1,000 times the earth's gravitational acceleration was needed. To secure this acceleration, two parallel steel rods are clamped at their midpoint and rotated by an adjustable speed D.C. motor. Fastened between the rods at their outer ends is a heavy steel plate to which is secured a mounting for the object under test. With the test object in place, the machine may be driven at the speed necessary to give the desired acceleration. After stopping the machine, the effect on the apparatus under test may be determined. Provisions are also made for observing the effect of the accelerations on the object as the speed of the machine is increased. A neon lamp is mounted to shine directly on the object when the arm is horizontal. At each rotation, this lamp lights for a few millionths of a second from an impulse generated in

a winding on a permanent magnet when a small iron bar attached to the rotating arm passes the pole pieces. For the rest of the time, the arm is in comparative darkness. This stroboscopic arrangement makes the arm appear to stand still in the horizontal position and any distortion of the test object can be observed while the acceleration is being increased.

Electric Lighting Installations for Building Interiors

IN A PAPER on this subject read recently before the Institution of Electrical Engineers, R. O. Ackerley examines the methods which should be adopted in order to answer the various questions which arise when designing an electric lighting installation. The paper stresses the importance of careful task analysis in the first instance to determine exactly what is the visual problem for which suitable lighting must be provided, and goes on to discuss methods of lighting, factors affecting illumination requirements, the selection of appropriate lighting fittings and lamps, and the calculations necessary to determine their location and wattage. The paper also deals with probable trends in lighting in the post-war period and the light sources and materials for light-control that are likely to influence them.

Modern Electric Lift Practice

A PAPER read by L. S. Atkinson before the Institution of Electrical Engineers reviews present-day electric lift practice by making brief reference to those aspects of the subjects which are the concern of the architect, and to the application of lift equipment to suit various classes of building. It explains the changes that have been made in general design from time to time to meet the problems created by the increasing height of buildings and their growing populations, and further describes the equipment as generally installed to-day.

Summer School in Social Biology

A SUMMER SCHOOL in Social Biology and Human Affairs will be held by the British Social Hygiene Council at University College, Nottingham, during July 28-August 11, under the directorship of Prof. Winifred Cullis. This School is designed for teachers and social workers, health visitors, superintendents of children's homes, industrial nurses, etc. Special consideration will be given to educational problems in social biology presented by the coming increase in the school-leaving age. Further information can be obtained from the British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Announcements

DR W. Q. KENNEDY has been appointed professor of geology in the University of Leeds.

AT a meeting of the Royal Astronomical Society held on April 13, the following officers were elected: *President*, Prof. H. H. Plaskett, *Vice-Presidents*, Dr. E. C. Bullard, Sir Harold Spencer Jones, Prof. E. A. Milne and Mr. F. J. Sellers, *Treasurer*, Mr. J. H. Reynolds, *Secretaries*, Dr. H. R. Hulme and Mr. D. H. Sadler, *Foreign Secretary*, Prof. F. J. M. Stratton, *Members of Council*, Miss M. G. Adam, Dr. H. A. Bruck, Rev. M. Davidson, Dr. M. A. Ellison, Mr. F. J. Hargreaves, Dr. A. Hunter, Dr. E. M. Lindsay, Captain W. N. McClean, Prof. W. H. McCrea, Dr. G. C. McVittie, Mr. P. J. Melotte and Dr. R. Stoneley.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Structure of Colchicine

THE suggestion of Dewar¹ that ring *C* of colchicine is 7-membered is interesting, and the arguments which he advances in favour of this merit consideration. I cannot, however, accept his statement that "Cohen, Cook and Roe have now provided evidence that ring *B* must be 7-membered". The paper² to which Dewar refers merely makes a tentative suggestion that ring *B* might be 7-membered. The only legitimate evidence that ring *B* of a degradation product of colchicine (namely, deaminocolchicinol methyl ether) is 7-membered is provided by experiments described in a paper by Barton, Cook and Loudon, recently submitted for publication in the *Journal of the Chemical Society* (and received by the Society on February 1). Consequently, Dewar's assumption in respect of the structure of this part of the colchicine molecule is based on unwarranted speculation. Incidentally, the work of Barton, Cook and Loudon fully establishes the methoxylation pattern of deaminocolchicinol methyl ether, and hence probably also the orientation of the substituents in colchicine.

¹ Dewar, M J S, *Nature*, 155, 141 (1945)² Cohen, A, Cook, J W, and Roe, E M F, *J Chem Soc*, 194 (1940)

My communication on this subject was written in ignorance of the work of Barton, Cook and Loudon, which was partly disclosed at a meeting of the Chemical Society, but is still unpublished. In relation to the facts known when I wrote, my remarks on the nature of ring *B* in colchicine can scarcely be described as unduly speculative. In any event I reserve any possible discussion for the time when all the facts are available. This question of the structure of ring *B* is, of course, important, but it can be settled by application of routine methods of alkaloid chemistry. On the other hand, the suggestion I have ventured to make regarding ring *C* is quite novel in this field.

Confirmation of the tropolone structure of ring *C* has now been obtained by the degradation suggested by me. Dr I Berenblum very kindly provided a small specimen of colchicine and this was converted to crude hexahydrocolchicine and submitted to lead tetra-acetate oxidation. About 0.6 molecules of lead tetra-acetate were rapidly consumed and considerable further oxidation took place more slowly. This behaviour would be expected in an unsaturated cyclic α -glycol¹. The oxidation product was aldehydic acid gave an amorphous mixture of dinitrophenylhydrazones. Although lack of material prevented purification of the hexahydrocolchicine or isolation of a definite oxidation product, it seems fairly certain that hexahydrocolchicine must indeed be an α -diol. If so, confirmation is provided for the tropolone structure of colchicine.

Previously² resonance chelation was postulated to explain the aromatic nature of the tropolone ring. Calculation shows that in such a structure the O—O distance would be about 2.51 Å and that the O—H bond would be stretched. It is possible, therefore,

that the resonance is an ionic one of the type postulated for colchicine³ and that tropolone forms a tautomeric system of high mobility. On the other hand, the great solubility in water of colchicine, in contrast to colchicine or stipitatic acid, is better explained if in it alone an ionic resonance (implying a semi-zwitterion structure) occurs.

It may be noted that puberulic acid⁴ is probably one of the three possible monohydroxystipitatic acids, and puberulonic acid the corresponding 'tropolone-quinone'. This relationship was pointed out by Birkinshaw, Chambers and Raistrick⁵, and the existing evidence is insufficient for further comment on the structures of those acids.

Metabolism of 3,4-Benzpyrene in Mice

If 3,4-benzpyrene is introduced into a mouse, it is eventually excreted as the phenol 8-hydroxy-benzpyrene^{1,2}. It has been established that this transformation proceeds by various steps^{3,4}. Four different benzpyrene derivatives have now been separated from extracts of various fresh tissues, they are provisionally termed X_1 , X_2 , F_1 and F_2 , because they are responsible for the 'BPX' and 'BPF' fluorescences that Peacock⁵ and Chalmers⁶ discovered in the liver, bile, intestine and faeces of various animals after application of benzpyrene. The separation of X_1 , X_2 , F_1 and F_2 has been effected by fluorescence chromatography and selective extraction, using alumina and silica as adsorbents and acetone, benzene, xylene, petroleum ether, methyl, ethyl and amyl alcohols and water as solvents. X_1 and X_2 occur *in vivo* not only in the liver and digestive system but also in the lung, kidney cortex, subcutaneous tissue, skin (after painting with benzpyrene), and in the mammary glands as evidenced by the milk of mice. F_1 and F_2 occur in the large intestine and faeces, and occasionally in the lungs. The amount of fresh uncontaminated mouse urine did not suffice for a definite analysis, but there were indications of the presence of the X derivatives. *Post mortem*, all X -bearing tissues show slowly increasing amounts of the F derivatives unless they are kept in formol. The 3,4-benzpyrene-5,8-quinone that Berenblum and Schoental² discovered in the faeces never appeared in fresh tissues.

The sequence of the metabolic conversion can best be seen by following the products through the digestive system. In the liver, X_1 is formed almost exclusively, and enters with the bile into the small intestine, where it is converted slowly to X_2 in the tissue of the wall. However, the bulk of the X_1 is changed to F_1 after its passage through the ileocaecal valve. In the later stages of the metabolism, more and more F_2 appears in the faeces. This sequence can be summarized by the scheme:

ABSORPTION SPECTRA (LOG ϵ) OF 3,4-BENZPYRENE (TOP), 8-HYDROXYBENZPYRENE (BOTTOM) AND FOUR INTERMEDIATE METABOLITES, X_1 , X_2 , F_1 AND F_2 , DISSOLVED IN ARBITRARY CONCENTRATION IN ETHANOL. THE TYPES OF THE GRAPHS ARE SIMILAR FOR Bp , F_1 , F_2 AND 8-HO-Bp BUT DIFFERENT FOR X_1 AND X_2 . THE WAVE LENGTHS OF THE LAST VIOLET BANDS OF THE ABSORPTION SPECTRA (INDICATED BY ARROWS) COINCIDE WITH THE FIRST VIOLET BANDS OF THE FLUORESCENCE SPECTRA OF THE COMPOUNDS (NOT INCLUDED IN THE FIGURE)

Of these transformations, (2) is the only one as yet that can be effected with the purified substances *in vitro*. It happens when the adsorbate of X_1 on alumina is heated above 150° C *in vacuo*, and slowly when X_1 is kept in dilute hydrochloric acid. This last change, with a simultaneous oxidation to the quinone, proceeds quickly at 100° C.

It has been established that F_1 and F_2 are phenolic, and that F_2 can act as a fluorescence indicator with a change of fluorescence colour from yellow to blue between pH 10 and 9.5. F_1 is strongly adsorbed from benzene and from petroleum ether to alumina with sky-blue fluorescence, F_2 less strongly with yellow-green fluorescence. They are soluble in organic solvents but insoluble in water. X_1 and X_2 are not phenolic, and both are strongly adsorbed from benzene and from petroleum ether to alumina with blue-banded fluorescence spectra, but silica adsorbs only X_2 from amyl alcohol. The X derivatives are soluble in water and in alcohols, but less soluble in benzene and in petroleum ether. The fluorescence spectra of all four derivatives in solution are of a similar type, and show three diffuse bands in the violet-blue distinguished by their position in the spectrum. Their absorption spectra show much more typical differences than their fluorescence spectra. In the accompanying graph, only the absorption spectra in the near ultra-violet and violet are recorded, because the compounds even after

chromatographic purification may contain cell constituents that absorb in the far ultra-violet. The last violet absorption band (marked by an arrow) coincides with the first fluorescence band of the compounds.

None of the derivatives has as yet been analysed owing to their instability and the small amounts that can be recovered from the fresh tissues of mice. However, the absorption spectra especially furnish some evidence of their chemical nature. F_2 has the same absorption spectrum as that published² for 8-OH-benzpyrene (appearing at the bottom of the graph), and it is probably identical with this phenol or a loose conjugate of it. F_1 has the same absorption spectrum except for the violet bands which are displaced by about 7 mμ towards the ultra-violet. This shows its close relationship with F_2 , but the stronger adsorption to alumina (and silica) of F_1 points to a higher molecular weight.

While the type of absorption spectra of the F derivatives is similar to that of benzpyrene itself (top graph) the absorption spectra of the X derivatives are different. Since it is known that the types of absorption spectra of benzpyrene derivatives with intact aromatic 5-ring nucleus are usually similar to each other, the different type of absorption of the X derivatives indicates that this nucleus is *not* intact. Hence the benzpyrene nucleus is altered during the transformation of benzpyrene into the non-phenolic X_1 , and it is restored when X_1 is changed to the phenol F_1 . Boyland and Levi⁷ observed such a phenomenon during the metabolism of anthracene by rats and rabbits. The urine contained the alcohol 1,2-dihydroxy-1,2-dihydro-anthracene with one double-bond less in the anthracene nucleus. This alcohol changes to the phenol 1-anthrol on addition of dilute hydrochloric acid, and the complete aromatic anthracene nucleus is restored. These reactions proceed as follows:

Fieser⁸ suggested the term 'perhydroxylation' for an addition of hydrogen peroxide followed by loss of water, and advanced the hypothesis that such a reaction might be responsible for the metabolic conversion of carcinogenic hydrocarbons to phenols. Hence it is likely that our non-phenolic benzpyrene metabolite X_1 , which changes easily into the phenolic metabolite F_1 is 8,9-dihydroxy-8,9-dihydro-3,4-benzpyrene or one of its conjugates. The stronger adsorption of X_2 on the chromatographic columns points to a higher molecular weight than that of X_1 .

Experiments on the carcinogenic properties of the various metabolites are in progress with Dr J C Mottram, to whom I am indebted for that part of the work concerned with the living animals.

Isolation of Asparagine from the Hæmolymph of *Melolontha* Larvæ

DURING a study of the amino-acids of the hæmolymph of insects, a substance was isolated from the blood of *Melolontha vulgaris* which turned out to be asparagine. This finding may be of interest because, to my knowledge, this substance has not been met with in animal fluids or tissues before, while it is a characteristic constituent of many plants.

The blood of some hundred larvæ (15 gm) was leprotenized with trichloroacetic acid, and the filtrate was freed from the acid by extraction with ether. Hexon bases and some peptide or peptides were precipitated with phosphotungstic acid, and carbonic acids were precipitated with barium hydroxide and alcohol. After concentration *in vacuo* and removal of barium with sulphuric acid, mercuric acetate and sodium hydroxide were added by drops until no further precipitate would form.

The precipitate was suspended in water, decomposed with hydrogen sulphide and after removal of mercuric sulphide the solution was concentrated on a steam bath. First tyrosine crystallized out and was removed, and the mother liquor was concentrated further. Irregular crystals of another substance now separated out. They were freed from the glassy mother liquor by digestion with warm 50 per cent alcohol in which the crystals were but little soluble. The substance was repeatedly recrystallized and the resulting sample of an apparently pure substance (10 mgm) was analysed after drying at 110° C. The results are presented below with the theoretical values for asparagine.

	Found (%)	Theory (%)
Total nitrogen	20.7	21.2
mino nitrogen (per mol titre)	11.0	10.6
mino nitrogen (4 hr hydrolysis with 1N hydrochloric acid)	9.2	10.6

The crystals resembled in every respect those of asparagine.

The concentration of asparagine in the blood of the larvæ can only be roughly estimated, due to the inevitable losses on recrystallization. 150–250 mgm per cent should be a probable guess. Blood from larvæ of the related *Oryctes nasicornis* was found to contain 23.7 mgm per cent amide nitrogen, corresponding to 223 mgm. per cent asparagine, but the material did not suffice for an isolation. So it still remains to be seen if asparagine is a peculiarity in *Melolontha* or a typical product of insect metabolism.

Antibacterial Activity of 2:6-Dimethyl-Penthiene-3·5-Dione

In a recent speculation Gulland and Farrar¹ have elaborated a hypothesis for the mode of action of *cyclotelluro-pentane-3·5-dione* and homologues, in which substrate competition with pyridoxin is postulated as a possible explanation of their high bactericidal activity. The structural resemblance of these tellurium compounds to that of pyridoxin is pointed out, and it is suggested that analogous substances containing an oxygen or a sulphur atom instead of tellurium might possess correspondingly high bacteriostatic or bactericidal activity without the extreme toxicity of the tellurium compounds.

As we were interested in heterocyclic ring compounds containing sulphur², we have prepared and tested the sulphur analogue of 2:6-dimethyl-cyclotelluro-pentane-3·5-dione, which is the most active representative of the tellurium series of homologues. 2:6-Dimethyl-penthiene-3·5-dione is a white crystalline substance of m.p. 124–125° C, soluble in hot water. It dissolves easily in cold caustic soda solution, but does not give a coloration with alcoholic ferric chloride except on prolonged standing, in which it resembles *cyclotelluro-pentane-3·5-dione*³. It forms a white crystalline dioxime of m.p. 181–183° C, slightly soluble in hot water. The accompanying table shows the results of the bacteriological examination and gives the minimum concentrations inhibiting the growth of one loopful of inoculum.

	<i>Staph aureus</i> NCTC 4163 glucose broth (18 hr at 37°)	<i>Bact coli</i> NCTC 86 Lemo broth (18 hr at 37°)	<i>Bact coli</i> NCTC 86 Reader's medium (24 hr at 37°)
	1 1,600 (1 600,000– 1 10,000,000)*	< 1 1,000 (1 9,000,000– 1 10,000,000)	1 6,400
	< 1 1,000	< 1 1,000	1 3,200
	1 1,000– 1 2,000	< 1 1,000	1 6,400

* The figures given in brackets are the bactericidal concentrations of the analogous tellurium compound reported by Morgan *et al*.⁴

Contrary to expectations, the compounds show little or no activity against the organisms tested. It is interesting to note that enolization, which is a prerequisite in Gulland and Farrar's speculation, in our case decreases or abolishes bacteriostatic activity altogether. The dioxime of 2:6-dimethyl-penthiene-3·5-dione, however, in contrast to the corresponding tellurium compound, is as active as the parent substance. It would appear, therefore, that other factors, apart from the arrangement $-\text{C}(\text{CH}_3)\text{C}(\text{OH})\text{C}-$, as suggested by Gulland and Farrar (*loc cit*) are fundamentally concerned in determining the bacteriological properties of this class of compounds. Our results certainly do not favour their speculation of substrate competition with pyridoxin.

Constitution of the Salivary Gland Chromosomes of *Chironomus*

SINCE the discovery of giant salivary gland chromosomes in dipterous larvæ¹, cytophysiologists have regarded them as the most favourable material for studying the chemical composition and fine structure of chromosomes, especially the leptonic relation between nucleic acid and protein. The view that chromosomes are chiefly composed of nucleoprotein is now generally accepted. In salivary gland chromosomes, the bands represent regions of relatively high nucleic acid content, while the interbands carry very little, if any, nucleic acid. The results obtained by Feulgen staining², histochemical tests³ and ultraviolet microscopy⁴ have all substantiated this conclusion. Digestion experiments by Caspersson and by Mazia and Jaeger⁵ clearly indicate that the salivary gland chromosomes possess a continuous protein framework the integrity of which is independent of the presence of nucleic acid molecules. In a more definite way, Astbury and Bell⁶ and Schmidt⁷ concluded from their X-ray diffraction and birefringence data that the most important elements in the molecular organization of the chromosomes are the partially folded and partially extended polypeptide chains, together with the parallel fitting of thymonucleic acid on to the extended portion of the chains. Based on this structural principle, Pfeiffer⁸ and especially Calvin and Kodani⁹ have proposed a probable structure for the salivary gland chromosome.

More recently, Stedman and Stedman¹⁰ announced the isolation of an acid protein which was named 'chromosomin'. They considered this to be the chief protein constituent of the chromosome, since its staining behaviour was the same as that of the chromosome. These authors also suggested that nucleic acid, instead of being attached to the chromosome, is present mostly in the nuclear sap. They questioned the reliability of the Feulgen technique as a means of demonstrating the actual location of thymonucleic acid, and interpreted the results of its application on a basis quite different from the hitherto accepted interpretation, which appeared to be supported by the success of staining plant chromosomes with 'developed nuclear stain'¹¹. These novel ideas at once attracted the attention of cytogeneticists, and an interesting discussion of the problem began¹².

Since the work of the Stedmans was done on vertebrate tissues, and since they made no comment on the structure of salivary gland chromosomes, which are large enough to permit of separation from the nuclear sap, we have made experiments on such chromosomes in *Chironomus* larvæ. (1) Instead of producing aldehyde groups by the hydrolysis of thymonucleic acid *in situ*, we allowed 5 per cent aqueous formaldehyde solution to react previously with leucobasic fuchsin *in vitro*, thus producing a 'developed nuclear stain'. The dye thus obtained stained the bands without hydrolysis in exactly the same way as in the standard Feulgen reaction. Nor was there any difference with respect to the differentiation between bands and interbands, if we first impregnated the gland cells with formaldehyde and then immersed them in leucobasic fuchsin. (2) When hydrolysis in normal hydrochloric acid at 60° was prolonged beyond 15 minutes, the chromosomes gradually lost their staining capacity toward the Feulgen reagent and eventually became entirely negative after 20–30 minutes hydrolysis. (3) Salivary gland chromosomes in smear preparations were first

excised and then thoroughly washed with insect Ringer to remove as completely as possible the surrounding materials. Such 'naked' chromosomes gave the same Feulgen reaction as when present in the intact nuclei. (4) In the 'naked' chromosome formaldehyde-developed Feulgen reagent produced typical banded structures without acid hydrolysis. Likewise, a pretreatment with formaldehyde followed by leucobasic fuchsin yielded essentially similar results. (5) Prolonged hydrolysis also made such 'naked' chromosomes behave negatively toward the Feulgen reagent.

In order to explain these results, we assume that the *Chironomus* salivary gland chromosome has a structure something like that proposed by Calvin and Kodani. The ability of chromosomes to take up basic dyes is normally due to the formation of salt-like compound of the latter with nucleic acid. The recent investigations of Kelley¹³ on the dyneucleoprotein reaction has offered confirmation, though somewhat indirect, evidence on this point. The results of our experiments (1) and (4) might seem at first sight to be in accordance with the Stedman view that the chromosomes consist only of acid protein, though the existence of banded structure in the chromosomes is difficult to explain. But the two experiments can equally well be interpreted by assuming nucleic acid to be present on the bands, especially if the perpendicular attachment of planar nucleoside molecules to the bands results in a structure of relatively high porosity and consequent in a greater imbibition of formaldehyde or developed fuchsin in these regions. The loss of staining power toward Feulgen reagent after prolonged hydrolysis (our experiments (2) and (5)) may well be due, as Bauer¹⁴ and Hillary¹⁵ have suggested, to the gradual splitting of a bond between the ribose and phosphoric acid within a nucleotide. But it is the result of our experiment (3) which is particularly hard to reconcile with the Stedmans' view. We certainly do not contend that the 'naked' chromosomes as prepared above are completely free from nuclear sap. But it seems certain that the quantity present would not be sufficient to produce the intense chromosome coloration by the standard Feulgen reaction, if nucleic acids were really present in the sap rather than on the chromosomes. Our experiments, at least those with 'naked' salivary gland chromosomes of *Chironomus*, strongly suggest the presence of nucleic acid in the chromosome.

Interaction of Nitrous Oxide and Hydrogen in the Silent Discharge

THE conductivity ι and nature of a discharge reaction have been shown to depend upon $V - V_m$, where V is the applied potential and V_m its 'threshold' value required to initiate ι .¹ This is illustrated by the varied results for the above reaction, found sensitive to small changes in the operative conditions. The interaction of nitrous oxide with hydrogen, like its decomposition, sets in only above V_m , this increases sensibly linearly with the pressure p , the corresponding total time of reaction rises rapidly with p due to decrease of $V - V_m$.¹

Compared with its thermal analogue² using different catalysts and a wide range of temperature and pressure, changes in the latter and particularly the ratio of nitrous oxide to hydrogen influence markedly the discharge reaction. Its course, with a small pressure (p) and large excess of hydrogen, is simplest p and $1/\iota$ eventually reach a minimum, and remain constant under continued discharge. The final products and p follow the equation $N_2O + H_2 = N_2 + H_2O$, this applies also to the thermal change.² As p is increased, p and $1/\iota$ decrease first slowly and later sensibly faster, these features are accentuated and the initial stage shortens as p and $V - V_m$ are increased. Thus, for example, at 400 mm and 4.3 kV, the initial stage was scarcely noticed, in 8 minutes, p dropped to 300 mm. and ι increased from 0.5 to 4.5 milliamp. At 560 mm and 5.1 kV, however, a sharp deprecitation-like sound was produced immediately the discharge was switched on, the consequent fall in p and $1/\iota$ (which was unsteady) were too large and sudden to follow.

An increase of the proportion of nitrous oxide produces strikingly different results. At low p , after an initial rise, p and ι fall to a constant minimum

As p increases, there is first a large and steep rise in p and ι , then a smaller and slower change in both to a maximum, and finally an overall diminution. A larger p , however, produces a remarkable periodic effect the frequency and duration of which increase rapidly with p and especially the ratio of nitrous oxide to hydrogen. The accompanying figure reveals a close similarity in the time-variation of p , ι and the corresponding energy dissipated in the system, W . As the reaction approaches completion, the successive fluctuations on the p -time curve are 'damped'. At 478 mm, 5.1 kV. and $N_2O/H_2 = 3$, the total time was so long that twenty pressure reversals of practically constant size were observed during about twenty hours. Since ι depends upon $V - V_m$, V_m should vary periodically corresponding to ι , this has been observed.

The nature of the glow also changed periodically. As p began to decrease, mobile brushes appeared, their number and intensity increased, and a pink violet glow grew from the annular surfaces, at minimum p it was practically free from brushes. Changes occurred in the reverse order during the ascending part of the cycle. The former spectral sequence was also observed during pressure diminutions with a large excess of hydrogen when the reaction progressed uniformly.

Nitric oxide, nitrogen and free hydrogen observed after short exposures suggest that the decomposition of nitrous oxide predominates in the initial stage,¹ this corresponds to the initial sharp rise in p and ι .

The subsequent slower rise in p and decrease of ι are attributed to the formation of nitrogen trioxide (N_2O_3) and nitrogen dioxide (NO_2).¹ Marked traces of ozone (ozone was also observed in the decomposition of nitrous oxide by silent discharge 1b) together with free hydrogen were detected corresponding to about the first maximum on the p -time curve,

oxygen and water were also observed. Likely interactions leading to products such as nitrogen pentoxide and nitric acid show the extreme complexity of the change.

In the so-called rhythmic and pulsating reactions the velocity, and not necessarily the direction of the change, varies periodically.³ The pressure and the associated synchronous changes especially during the later stages of the present reaction, however, indicate that the corresponding *direction* is reversed periodically. The entire group of these fluctuations was suppressed when the ozonizer was cooled to 7° C, and revived on restoring the temperature. An alternate film-like condensation and evaporation (or/and desorption) is, however, insufficient as a general explanation.⁴ Moreover, attempts to observe such a periodic effect in vapours of water, bromine and iodine under similar conditions of discharge have failed.⁴ That the periodic effect does not necessarily accompany at any rate a partial reversal of reaction was observed in the interaction under

INTERACTION OF NITRIC OXIDE AND HYDROGEN IN THE SILENT DISCHARGE. INITIAL PRESSURE, 23.2 CM. MERCURY, APPLIED POTENTIAL, 2.7 KV (50~), $N_2O/H_2 = 0.61$

discharge of sulphur and nitrogen⁴. During subsequent work on the behaviour of the above products of the nitrous oxide-hydrogen interaction, reversal of change and also a full periodic effect as in the accompanying figure are observed under certain conditions of the decomposition of nitrogen dioxide by the silent discharge⁴.

Compounds of the Structural Type of Calcium Titanate

In a previous communication¹, it was recorded that precision X-ray powder methods with a large-diameter camera show that the structure of nickel oxide is not strictly cubic, but only pseudo-cubic. Splitting of some of the X-ray reflexions into more than one component is explained if a small distortion of the cubic lattice along an octahedral axis is assumed, so that the true symmetry is rhombohedral hexagonal.

In the course of investigations on compounds of the structural type of perovskite, CaTiO_3 , it has been found that precision powder methods are capable of demonstrating that only a minority of these crystals have cubic symmetry. Naray-Szabo^{2,3} has recently examined many crystals of the calcium titanate type by means of oscillation diagrams, and has shown that several, including perovskite itself, are monoclinic, and others, for example, lead titanate, are tetragonal or orthorhombic. Using the powdered crystal technique, the differentiations described by Naray-Szabo have been, in general, confirmed, although a small distortion from cubic symmetry has been observed for barium titanate, which is still classed as cubic by Naray-Szabo.

The X-ray powder photographs may be grouped into three main types. For compounds typified by strontium titanate the lines fall in the sequence demanded by the ideal cubic structure. No extra reflexions occur and no splitting of the main reflexions can be distinguished. The ideal cubic structure is therefore valid to a high degree of accuracy.

For some other compounds, of which barium titanate is an example, many of the powder lines are split into more than one component, and the new features can be explained if the symmetry is assumed to be tetragonal. The measured lattice constants of barium titanate are then $a_0 = 3.9866 \text{ kX}$, $c_0 = 4.0195 \text{ kX}$ at 22°C . For lead titanate a still greater distortion of the structure is revealed, the axial ratio being much further removed from unity.

With a larger group of compounds the main powder lines show many complexities and a number of extra reflexions appear in intermediate positions. Part of a powder photograph of calcium stannate is reproduced herewith to indicate the kind of effect which is observed. The main groups of lines have been indexed according to the old cubic structure. One noteworthy

PART OF X-RAY POWDER PHOTOGRAPH (COPPER $K\alpha$ RADIATION, 19 CM CAMERA) OF CALCIUM STANNATE (CaSnO_3).

and characteristic feature of the X-ray pattern of crystals of this type is that a low-order line (x) appears the spacing of which is $2/\sqrt{5}$ that of 100. This indicates that the indices of the main lines should in fact be doubled, and therefore, when an approximation to cubic symmetry is assumed, the unit cell dimensions must be twice those of the ideal perovskite unit cell. For example, the side of the pseudo-cubic unit cell of calcium stannate is approximately 7.87 kX , and not 3.935 kX , the lattice constant for the old structure.

It will be seen that all the members of this large class of compounds, having the general formula ABO_3 , cannot be regarded as isomorphous in the strict sense of the term. Although the ideal lattice has cubic symmetry, in the majority of cases, the cubic structure is appreciably distorted and the true symmetry may be tetragonal or more often monoclinic. There are, no doubt, other groups of compounds, the members of which have similar structural relationships, which would not be embraced by the term isomorphism as at present understood. Naray-Szabo³ suggests that such related structures should be described as 'sister' structures. An alternative would be to use the term 'pseudo-isomorphous' to denote the close structural similarities. This would have the advantage that it follows the accepted custom of using the prefix 'pseudo' to denote structures that are distorted but closely related to the more symmetric crystal systems.

Crystal Structure of Barium Titanate

It is well known that barium titanate belongs to the group of compounds having structures of the perovskite type¹. The ideal perovskite structure ($G5$ in the "Strukturbericht") has a simple cubic lattice, with one formula-weight per cell, the atomic parameters being as follows: 2-valent cation, $(0,0,0)$, 4-valent cation, $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$, oxygens, $(0, \frac{1}{2}, \frac{1}{2})$, $(\frac{1}{2}, 0, \frac{1}{2})$, $(\frac{1}{2}, \frac{1}{2}, 0)$. It was early recognized² that for many of these compounds, including perovskite (CaTiO_3) itself as well as barium titanate, the structure was not truly cubic but was actually a slightly deformed modification of it. Perovskite itself is generally believed monoclinic, the structure has recently been determined in detail by Naray-Szabo³, who finds a monoclinic unit cell with all its edges doubled relative to the unit cell of the ideal structure. No detailed work on barium titanate has hitherto been published, and it was thought of interest to investigate it. Powder photographs of the synthetic material taken in a 19 cm diameter camera with copper $K\alpha$ radiation provided the data for determining the structure.

The structure is tetragonal, the dimensions of the unit cell at 20°C , for a typical sample of material,

being as follows: $a = 3.9860 \pm 0.0005$ kX., $c = 4.0263 \pm 0.0005$ kX., $c/a = 1.0101 \pm 0.0002$. This cell contains one formula-weight, BaTiO_3 . The atomic parameters are the same as in the ideal cubic structure. The relationship between the tetragonal and cubic structure is close; the tetragonal unit cell may be simply derived from the cubic by stretching it homogeneously by about 1 per cent along one tetrad axis, which becomes the c axis.

This close relationship suggests that a transition to the cubic structure may occur at higher temperatures. This was verified from photographs taken with a high-temperature camera. At 200°C ., barium titanate has the ideal cubic structure, with $a_0 = 4.0040 \pm 0.0005$ kX.

Further work is in progress.

I wish to express my gratitude to Sir Lawrence Bragg for allowing me the use of the high-temperature camera in his laboratory. I wish also to thank Mr. J. A. M. van Moll (head of the Material Research Laboratory) and the directors of Philips Lamps, Ltd., for permission to publish this work.

Abrasion of Porcelain Balls

In *Nature* of August 5, 1944 (p. 169), Lord Rayleigh gives a very interesting description of the production of pebbles of regular shape by laboratory abrasion tests. His main conclusion seems to be that pieces of marble of apparently homogeneous texture tend to become oblate or prolate spheroids even though they start from shapes that are roughly cubic or spherical.

We have recently observed a phenomenon that seems far more mystifying, namely, the tendency of porcelain balls when used for grinding refractory materials in a ball mill to assume a roughly cubic

shape. The samples shown in the reproduction at approximately actual size were originally essentially spherical and assumed this dice-like shape after a few months of service. Their original size was approximately twice that shown. The manufacturers of these balls state that they are made by extruding a cylindrical column of batch, cutting this off into lengths, and rolling to give sphericity. Had the extruded section been square an obvious explanation would have suggested itself.

Nomenclature of Animal Behaviour

Dr. J. S. Kennedy and Dr. D. L. Gunn¹ have discussed the difficulties inherent in the creation of new technical terms in connexion with animal behaviour. Recently Donisthorpe and I have listed (in a paper now in the press²) the specialized scientific terms used in describing and classifying the behaviour of ants. So far as possible, terms used generally in entomology and other branches of biology have been omitted, except where they have a special myrmecological meaning. One hundred and seventy terms have been listed, and each one has been defined, the original author of the term being cited.

In many cases the original definition of a term is inadequate, or common usage may slightly change its meaning, and in such cases a new and, we hope, adequate definition has been given. Numerous synonyms occur, and in such cases both terms have been defined and included in the list. No attempt has been made to 'sink' one term or another.

I hope that when myrmecologists throughout the world have considered this list with its definitions and synonyms, and have pointed out any omissions, then it will be possible to decide by common consent to use certain terms and not others, and to set up a standard myrmecological terminology. It is to be hoped that this process may be continued throughout the biological sciences; but, to my mind, the first and essential step in the process is the listing and defining of the already existing terms.

I agree with Dr. Gunn that the use of common words as technical terms should be avoided. A flagrant case of this exists in myrmecology in the restriction of the terms 'mixed nests' and 'compound nests'. Wheeler³ defined 'mixed nests' as colonies of ants which are composed of more than one species, and in which the brood is not kept separate; and 'compound nests' as colonies of ants which are composed of more than one species, and in which the broods are kept separate. This is most confusing to the non-specialized biologist, and destroys both the natural collective terms for colonies of ants which are composed of more than one species. To get over this difficulty I have recently proposed⁴ the term 'mixtobiosis' to include all cases of mixed and compound nests of ants.

THE BRITISH EMPIRE CANCER CAMPAIGN

ANNUAL REPORT

IN the introduction to the twenty-first annual report of the British Empire Cancer Campaign, the honorary secretary, Mr. J. P. Lockhart-Mummery, says that "it is a matter of satisfaction that, at the end of five years of war, cancer is being studied in this country with even greater intensity than before". It is indeed remarkable that so much progress should be made. Soon the work should be accelerated.

When proposing the adoption of the report, Prof. F. L. Hopwood directed attention to the possibility of introducing radioactive elements in non-toxic compounds into the body. In this way local concentrations of radioactive material in particular organs or tissues might be achieved. Such a new technique would require expensive equipment for the preparation of radioactive elements, and the work would not be without risks for the operators; but interesting results should be obtained.

Therapy. The treatment of cancer of the prostate with oestrogens has been developed during the past year. The present report gives further evidence of the effectiveness of this treatment. The benefits of therapy have been maintained for long periods in many cases. Cancer of other organs has also been treated with oestrogens. Thirty-six cases of late cancer of the breast have been treated with trichloroethylene or stilboestrol at the Royal Cancer Hospital and the Christie Hospital, Manchester. Of these cases, fifteen showed temporary retardation of the growth, although the effects were in general less than could be expected from local palliative X-irradiation. Of twenty-nine cases of advanced cancer of organs other than prostate and breast, only one (a case of carcinoma of the bladder) showed undoubted partial retrogression. Triphenylmethylethylene was less effective than either stilboestrol or triphenylchloroethylene.

Experiments on chemotherapy of cancer carried out by Dr. A. Haddow and Prof. G. A. R. Kon have been concerned with the action of symmetrical diphenylethylene derivatives. Two of these compounds are especially active in checking tumour-growth in animals.

Carcinogenesis. Studies in carcinogenic action during the past year appear to have been concerned with the elucidation of the action of known carcinogenic agents rather than with the search for new compounds. Carcinogenic agents inhibit body-growth, but this inhibition is most unlikely to be solely due to deprivation of cystine, as had been suggested by American workers.

2-Acetylaminofluorene has been further investigated by Prof. H. N. Green and Dr. F. Bielschowsky. This substance induces liver tumours and a few mammary tumours in rats. Liver damage is probably the primary change, and as a result oestrogens in the body are not metabolized and so may cause an increase in the number of mammary tumours. 2-Acetylaminofluorene does not normally induce tumours of endocrine glands, but in an experiment in which rats were treated with the carcinogen and allylthiourea to stimulate the thyroid, adenomata of the thyroid were induced. Allylthiourea itself induces hyperplasia of the thyroid but is not carcinogenic. Thus acetylaminofluorene is able to induce tumours

in hyperplastic thyroid tissue but not in the normal gland. No liver tumours have apparently been induced in mice treated with acetylaminofluorene in the Sheffield laboratories. Aminofluorene has pronounced bacteriostatic action *in vitro* and this action is inhibited by blood and tissue extracts. Mouse liver gives a much more potent antagonizing extract than does rat liver. 2-Acetylaminofluorene has been isolated from the urine of rats as a metabolite product of the carcinogen.

There is considerable variation in the response by different species or even by different strains to carcinogenic agents. Thus, although coal tar will produce tumours on the skin of mice and rabbits, many hydrocarbons that induce skin tumours in mice will not do so in rabbits. Dr. I. Berenblum has now found that the potent carcinogen, 9:10-dimethyl-1:2-benzanthracene, will produce skin carcinomas on the ears of rabbits. Experiments are proposed to determine if this compound will also induce skin tumours in rats and guinea pigs, which are resistant to most carcinogenic agents.

Dr. A. Glücksmann suggests that the sensitivity of mouse skin varies with the density of the hair coat. The hair follicles act as germinative centres, and the onset of ulceration and papilloma formation coincide with certain phases of the normal hair cycle.

Examination of lubricating oils for carcinogenic activity had made it possible for the Manchester Committee on Cancer to recommend oils which would be expected to be non-injurious from an examination of physical properties. Owing to war conditions, however, the safer oils were not available for some time and there was an increased amount of illness and even death due to epitheliomata of the skin of mule spinners and other workers in cotton mills.

Oestrogenic substances. The possible carcinogenic effects of a number of oestrogenic stilbene derivatives on the skin of mice have been investigated at the Middlesex Hospital. Of thirteen substances tested only one, α -ethyl- β -sec-butylstilbene, induced skin tumours. This compound is but feebly carcinogenic to skin, as only two tumours occurred in twenty-one mice that survived a year of treatment. Attempts to find water-soluble oestrogens have led to the synthesis of sodium hexoestrol phosphate and stilboestrol potassium sulphate. The biological action of aqueous solutions of both these products is being explored both *in vivo* and *in vitro*.

Tumours in pure-line mice. The occurrence of spontaneous cancer in pure-bred strains of mice may be related to other characters of the mice. Thus Dr. F. L. Warren has confirmed the American findings of lowered haemoglobin in the blood of female mice of strains liable to mammary cancer. The strain of CBA mice kept at the Royal Cancer Hospital has a low incidence of mammary cancer, and the mice appear to live longer than mice of strains in which mammary cancer is common. The ovaries and adrenals of mice of this strain have distinct histological differences from corresponding organs of other strains, in which mammary cancer is often seen. The mean concentration of ascorbic acid in the livers of mice of strains with a low incidence of mammary cancer is often lower than the concentration in the livers of mice from high cancer strains.

Dr. G. Bonser, of Leeds, has induced testicular tumours in mice of a number of strains by treatment with oestrogens. The milk factor, or mammary tumour inciter, appears not to influence the incidence of these tumours, but no testicular tumours were

obtained in the CBA strain (a low mammary cancer strain) while all the treated mice of the Strong A strain developed tumours. Other strains gave intermediate responses: the 'white label' and *IFS* strains gave a few tumours, and the *RIII* strain a moderate number of testicular tumours if the mice lived long enough.

The British Empire Cancer Campaign has been concerned with research for twenty-one years and is now taking on the additional duty of advising medical practitioners as to the value of any new form of treatment about which the Campaign has knowledge.

E. BOYLAND

GENETICAL ASPECTS OF THE CANCER PROBLEM

A "PRELIMINARY Report on a Survey of the Situation in Cancer", by Dr Fritz Blank, appears in the *Archives of Surgery, Chicago* (49, No 5, 301, 1944). The general interest of the study warrants a digest showing the limits of the field surveyed and the findings. In his foreword, Prof F. A. E. Crew points out that this survey of the biological background in cancer is the first major attempt by the Bureau of Human Heredity (115 Gower Street, London, W.C.1) to present the results which can be achieved through the 'clearing-house method'. It has been made possible by international collaboration between the Institute and the Department of Medical Genetics of Ohio State University, both of which are foci of much friendly co-operation between individual workers and numerous institutes.

The Bureau of Human Heredity has been developing the mechanism for such work as this since it opened in 1936. The method by which the cross-reference index is made is best compared to a great sorting machine. The desiderata were outlined early on by Profs R. A. Fisher and J. B. S. Haldane in consultation. It works well, three thousand sections on constitution and traits were already available when Dr Blank began the cancer collection, points in the present survey can be set against a further 1,500 or so. This preliminary survey covers most of the literature between 1900 and 1941, with data from about four thousand papers.

The summarized genetical findings are not the less important for presenting no surprises. The myth of hereditary cancer is disposed of. Geneticists are more and more aware in other fields of the fact that hereditary make-up controls type of constitution, in other words, individual variations in physiological function. There is evidence from many sources that carcinogenic agents react differently on various types of constitution. This would be expected from physiological genetics. An illuminating point may be gleaned here, namely, that certain types respond quickly to diverse kinds of irradiation. In another series it appears to be mainly hormone imbalance which prepares the body for growths and/or malignancy. Fortunately, data give at least a rough guide as to means of differentiating between these two major sources of the disease.

It is significant to learn that certain diseases of hereditary type appear frequently as precursors of neoplastic growth and malignancy. Here the clearing-house method may have special importance. Practi-

tioners, by contributing their observations to the Centre, will do much to accelerate accumulation of knowledge of practical value to their colleagues and to humanity.

Dr Blank's survey is set out in chapters dealing with those aspects in which research was sufficiently advanced in 1940 to show a bearing on the biological background, no reference is therefore made to the data on nuclear division, including polyploidy and extrachromosomal factors, on which researches are now in progress. Statistics come first of high genetical interest are comparative figures for different parts of the world and different races. These show that for all those areas and peoples for which reliable figures are available, the general incidence of cancer is practically the same, although site and type of the disease vary greatly, and there is a hint in the Dutch East Indies that hereditary racial characteristics underlie this fact where Malays and Chinese working side by side demonstrate racial incidence comparable to that of their home areas.

Detailed studies in Norway (Waaler, 1931), later repeated by Wassink in Holland, throw light on the question in general and show the complexity of the problem. Greenwood's analysis is as follows: (1) "some forms of cancer (e.g. lip cancer) are produced quite independently of any inheritable *anlagen*, extrinsic factors have greater, perhaps exclusive, influence upon males, (2) the heritable factors show two independent factors, both of which occur with a frequency of about 16%." These, according to Wassink, are the existence of a general predisposition and also a tendency to certain localization.

'Cancer families' are reviewed, beginning with studies in 1856, it has been shown that simple statistical study here is unreliable (Cramer, 1937), since in large families where sibs survive to thirty-five years, the expectation will be approximately that of the general population. Twin studies are mentioned, but since none conforms to the criteria set up by von Verschuer and Kober, the findings are omitted from the general argument.

The work on rodents receives notice proportionate to its importance and covers spontaneous tumours and the reaction of different strains to transplantation and induced tumours. In each series sharp differences in incidence and reaction are noted between stocks within any given species or variety: there are immune, partially immune or tumour-prone. There remains an unresolved problem here in a change of average incidence in experiments with foster suckling (the so-called milk factor). But here also a variation in resistance of the stocks persists, recent work on agglutinogens in milk were not available at the date to which the survey is carried.

Carcinogenic agents are surveyed in detail, the organic type, the viruses, have been the focus of the search for a possible causative factor or prime agent. Occupational cancers stimulated research on chemical agents, and these are reviewed. Work with hormones proceeding over the same period is not unrelated to those investigations, of these, oestrin has given important results, namely, the production of mammary cancer in 100 per cent of male mice in a cancer-prone stock. Cramer and Horning relate this to a heritable faulty metabolism shown as 'brown degeneration of the adrenals'.

Of great practical interest are the data on those diseases with genetic background which are frequent precursors of cancer. These are spoken of as the internal carcinogenic environment. In addition to

neuro-fibromatosis and xeroderma pigmentosum, achlorhydria is typical. The racial data demonstrate a constitutional susceptibility to physical irritants, particularly radiation. The work of Roffo and Findlay calls for further research in this direction although the general facts are clear.

Dr Blank concludes that the complexity of factors noted above will be found to prevail equally in most forms and types and sites of tumours. As the cases of cancer in which we can trace direct hereditary transmission are rare, admittedly they cannot provide a valid answer to the question of whether, or to what extent, an inherited susceptibility plays a part in the general incidence of malignancies. From disorders indicating a purely hereditary proneness to tumour formation, such as xeroderma pigmentosum or neuro-fibromatosis, must be differentiated many other types of tumour formation about which nothing yet is known of an inherited tendency as, for example, cancer of the lip, which according to Waaler seems to be distributed quite independently of any inherited disposition.

Much remains to be done before these problems can be solved, but our task will be lighter if we heed the lesson already taught, namely, that it is vain to ask, "Is cancer hereditary?" and that we must inquire *separately* for each organ, tissue and type of the disease, whether any hereditary factors, *direct* or *indirect*, are involved in a specific form of the malady.

Summarizing our present position meanwhile, we can say that enough evidence has been accumulated to warrant at least the following statements: (a) Cancer is not a unit disease, at least so far as its genetical behaviour is concerned. Tumours of different sites and types differ in their genetical behaviour. (b) Therefore it is unlikely that a heritable condition of 'cancer' exists as such. (c) There does exist a general inherited disposition, whether of susceptibility or refractoriness to tumour formation. (d) In certain individuals factors exist, most probably inherited quite independently of a general disposition, which govern the localization of the disease. This localization in turn seems to depend upon a favourable 'internal environment' in certain tissues or organs. (e) If general susceptibility and inherited favourable internal environment are combined in an individual, these factors may be strong enough in themselves to lead to cancer formation in certain tissues. (f) If general susceptibility is very marked in an individual, even relatively slight irritation by agents of many kinds may lead to cancer formation. (g) But quite apart from these heritable conditions, there exist purely external carcinogenic agents of various kinds, which are obviously strong enough to lead to cancer-formation in certain tissues, even in individuals in whom there is no inherited predisposition, or perhaps it is too weak to be detected by methods used at present in testing for hereditary traits.

The above is a picture of cancer research as seen by the genetically minded physician. The chief aim of the survey has been to show that the whole problem of heredity and cancer is a biological question of highly practical bearing. The writer endorses MacDowell when he says "It is highly regrettable that outside the immediate circle of geneticists, there seems to be an impression that the gene is self-sufficient and is either dominant or recessive. Especially as applied to neoplasms, this misunderstanding has led to erroneous conclusions both on

the part of hostile critics and ardent believer. Dominance is only a special case at the end of continuous series of interrelations between pairs of genes. No gene can produce its effect without the cooperation of many other genes. An genes and extrinsic conditions cooperate in all cases'.

ANTHONY FEILING

POPULATION PROBLEMS IN BRITAIN

SIR W LANGDON-BROWN, addressing the British Social Hygiene Council on the relation of social biology to the population problem (*Brit Med J*, 766, Dec 9, 1944), said that he regarded with grave suspicion the efforts of planners to dethrone the family and hand children over to the State. Some family life is unsatisfactory, but the majority is good. The birth-rate in Britain has fallen steadily since 1870 and, in the same period, the infant death rate had decreased and expectation of life had lengthened. There is evidence that the fertility rate decreases with improved chances of survival. The British Social Hygiene Council has estimated that one-tenth of all marriages in Britain remained childless, but not deliberately so. A study of 2,000 cases suggested that in 60 per cent there was a defect on the man's part. In general, the average male fecundity is much lower than was generally assumed.

Other factors operating against the family are increased rents and rates, which absorb much more than the one tenth of income allowed for these in the Victorian scheme of things. This means that money which should go for food is spent on housing with alarming effects on infant mortality and family life. There is an increase in life in flats due to aggregation of urban populations, and flats are unsuitable for children. A standard rate of family allowances would not be satisfactory. The effects of late marriages and the consequent celibacy forced on our younger people by social changes must be recognized and studied by social biologists.

These and allied problems are the subject of a booklet issued by the Tory Reform Committee entitled "Tomorrow's Children" (P. S. King and Staples, Ltd., 14 Great Smith Street, London, S.W. 1, 1s net). This pamphlet rejects the thesis that the world will get too full in the future, because effort to raise the birth-rate cannot do more than arrest the decline and because the progress of invention and science is always enabling us to support far greater populations at a higher standard of living. The maintenance of these greater populations depends on the fathers and mothers of the next thirty years. The problem before us is whether there will be enough people to keep things going when our grandchildren are grown up. Immigration may affect this problem considerably. Before this War, 50,000 more persons a year were entering Britain than were leaving it. In the future, Britain may attract thousands of the peasant populations of eastern Europe, and we may then be glad to let them in just as the Dominions and the United States were before the War of 1914-18. But at present we are faced with a progressive decline of the population. The apparently satisfactory conditions at present are due, not to a good birth-rate, but to a low death rate, resulting from improvements in public health which allow more old people to survive. The raising

of the net reproduction-rate to 1, instead of the existing rate of 0.75, which this pamphlet recommends as a practical policy, would tend to stabilize the population at about three-quarters of its present figure.

The trend towards a rapid decline of population affects not only Great Britain, but also Norway, Sweden, France, Belgium, Switzerland and Austria, where populations will decline at about the same rate as Britain's will. Other countries, including Ireland, Germany, Italy, Russia, Japan, China and India, will show an increase by 1970.

Among the causes of the population decline the pamphlet discusses (1) the enormously higher standard of living, leisure and comfort, (2) the great increase in mobility, which often makes the home into a place to be left as often as possible, (3) the almost universal literacy and widened outlook, due to reading in the local libraries and daily papers and to the radio, (4) the wide availability of contraceptives, which tend to affect the birth-rate in the groups of higher income and education, and (5) profound changes in our conceptions about religion, duty and social behaviour.

In Britain there is no spiritual significance of parenthood comparable to that which exists in India and China. Education stresses the importance of the individual, so that the child tends to ask what it can get out of life, rather than what it can give.

Among the remedies proposed by the Tory Reform Committee is the creation of a domestic service, which would make housework an attractive career. It also suggests that positive action should be taken in Parliament to bring this whole problem of population and family life more frankly before the people, to remove economic barriers to early marriage and to make two, three or four children an economic possibility in all classes, instead of a severe liability as they are at present. The alternatives against which the young married couples of the next few years can protect us if we enable them to do so are, the Committee thinks, decay through a progressively declining population, or immigration from countries with growing populations, including those of the East.

G. LAPAGE

POLLEN ANALYSIS AND THE MUSEUMS

HA HYDE, of the National Museum of Wales, has published an informative article on the technique, history and applications of pollen analysis (*Museums J.*, Dec 1944).

The study of atmospheric pollens in England began in 1867 when Charles Blackley, a Manchester medical practitioner, exposed to the air micro-slides treated with an adhesive, and found that the days when he slides showed most pollen grains coincided with those on which his hay-fever patients suffered worst.

In 1941 a detailed day-to-day census was begun at Cardiff, and the results obtained during 1942 (see 'Studies in Atmospheric Pollen I. A daily census of pollens at Cardiff, 1942'). By H. A. Hyde and Dr D. A. Williams (*New Phytol.*, 43, 49, 1944) showed that the effective pollen season lasted from early March until late September, and (as previously discovered in the United States) presented three phases characterized by the pollens of trees, grasses and other herbs respectively. The applications of pollen research are numerous. At Cardiff the work is maintained chiefly for the purpose of assisting

medical allergists in making their diagnosis, but in addition because it is of value in the pollen analysis of peat, in experiments on the hybridization of plants, and in meteorological work concerned with the movement of air currents. Again, pollen analysis has been employed—notably in Central Europe—in the determination of the source of origin of honey, and the author suggests that in the future bee-keeping and other departments of horticulture are likely to benefit from similar research. In this connexion he directs attention to the fact that the kinds of pollen collected by certain species of bees are already being investigated under official auspices.

Geological or archaeological correlations are probably the most widely known applications of pollen analysis, but the work so far carried out does not yet provide a complete and independent time-scale for dating archaeological finds. It has, nevertheless, made possible the reconstruction of the forest history of England and Wales since the close of the last Ice Age, and the working out of a number of correlations with human culture periods.

At the end of his paper the author suggests that "(pending the establishment of an institute of palynology)" at least the national museums should carry out fundamental pollen research, and that the larger regional museums might consider undertaking certain aspects of the work. In support of the desirability of this, he points out that certain public authorities in the United States carry out daily analyses of atmospheric pollens, and he is of the opinion that it will not be long before similar observations will be required in Great Britain. Collaboration between museums and public health authorities (both often under the same municipal authority) would, therefore, be of mutual advantage.

FORTHCOMING EVENTS

Saturday, April 21

SOCIETY OF INSTRUMENT TECHNOLOGY (at the London School of Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 11 a.m.

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at Caxton Hall, Westminster, London, S W 1), at 2.30 p.m.—Mr E. Mackie "A Consideration of the Requirements for Micrography and Cinemicrography Apparatus"

Monday, April 23

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Sir Frank Smith, G C B, G B E, F R S "Chemicals from Petroleum" (Cantor Lectures, 2)

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S W 7), at 5 p.m.—"Enthronement of the Dalai Lama, and Journeys in Bhutan" (Kodachrome Films by Sir Basil Gould, with Commentary by Colonel F. M. Bailey)

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Discussion of "Electrical Aids to Public Speaking" (to be opened by Mr P. G. A. H. Voigt)

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (PHARMACEUTICAL GROUP) (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N W 3), at 7.30 p.m.—"Some Interesting Facts on Sex-determining Compounds" (based on work by Mr R. Kuhn)

Tuesday, April 24

SOCIETY OF CHEMICAL INDUSTRY (NEWCASTLE-UPON-TYNE SECTION) (in the King's Hall, King's College, Newcastle-upon-Tyne), at 6 p.m.—Dr M. P. Appleby "The Chemist and the Air" (First Dunn Memorial Lecture)

Thursday, April 26

LINNEAN SOCIETY OF LONDON (joint meeting with the ZOOLOGICAL SOCIETY OF LONDON) (at Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Sir Frank Colyer "Caries of the Teeth in Animals", Dr Clara M. Warren "Fungus Infections of the Skin", Mr V. V. Tchernavin "Description of Five Specimens of Lyomeri (Deep Sea Fishes) preserved in the British Museum, with Notes on their Skeletons", Mr C. J. A. Berkeley "The Ovale of *Digitalis purpurea* Linn."

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Sir Edward Appleton, K C B, F R S "The Scientific Principles of Radiolocation" (Thirty-sixth Kelvin Lecture)

Friday, April 27

ROYAL INSTITUTE OF CHEMISTRY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 p.m.—Dr J. H. Quastel, F R S "Soil Metabolism"

ROYAL INSTITUTION (at 21, Albemarle Street, London, W 1), at 5 p.m.—Prof F. A. Buxton, F R S "Natural History of Scrub Typhus"

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2), at 6 p.m.—Mr S. Rodda "Beam Tetrodes"

Saturday, April 28

NUTRITION SOCIETY (joint meeting with the BIOCHEMICAL SOCIETY) (at the London School of Hygiene, Keppel Street, Gower Street, London, W C 1), at 11 a.m.—Discussion on "The Vitamin-B Complex"

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (joint meeting with the MIDLAND BRANCH) (at the University, Edmund Street, Birmingham), at 2.30 p.m.—Dr H. Kuhn "Atomic and Molecular Beams"

Sunday, April 29

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N W 3), at 11.30 a.m.—Dr B. Burzyn "On Recent Applications of Thermo-setting Resins on Paper and Textiles"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ENGINEER by the Government of Iraq to take charge of the Central Technical Section of the Directorate of Municipalities—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting C 2378 A) (April 26)

DEPUTY ELECTRICAL ENGINEER to the Stalybridge, Hyde, Mossley and Dukinfield Transport and Electricity Board—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting D 1170 XA) (April 26)

BOROUGH ELECTRICAL ENGINEER AND PUBLIC LIGHTING SUPERINTENDENT—The Town Clerk, Town Hall, Morley (endorsed 'Borough Electrical Engineer') (April 30)

ASSISTANT MASTER to teach SCIENCE in the Junior Technical School and in part-time Engineering and Building Classes in the Hinckley Technical College (special qualifications in CHEMISTRY would be an advantage)—The Director of Education, County Education Offices, Grey Friars, Leicester (May 3)

MANAGER for an important Division of well-known Precision Engineering Company (good engineering degree or equivalent professional engineering qualification will be regarded as essential, in addition to technical, commercial and production experience)—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting C 2550 XA) (May 5)

ASSISTANT LECTURER in the MECHANICAL ENGINEERING DEPARTMENT—The Principal and Secretary, Harris Institute, Preston (May 7)

SENIOR LECTURER (woman) in APPLIED MATHEMATICS—The Principal, Royal Holloway College, Englefield Green, Surrey (May 8)

SUPERINTENDENT OF TECHNICAL SUBJECTS (candidates must have an Honours Degree in MATHEMATICS and/or SCIENCE) to the Glasgow Education Department—The Director of Education, 129 Bath Street, Glasgow C 2 (May 12)

DEMONSTRATOR (man or woman) in the PHYSIOLOGY DEPARTMENT—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, London, W C 1 (May 18)

PRINCIPAL of the DARWEN TECHNICAL SCHOOL—The Divisional Education Officer, Education Offices, Darwen, Lancs (May 31)

ENGINEER to the Clyde Navigation Trust—The General Manager and Secretary, Clyde Navigation Trust, 16 Robertson Street, Glasgow, C 2 (endorsed 'Engineer') (May 31)

READER (full-time) in INDUSTRIAL HEALTH—The Secretary of University Court, The University, Glasgow (June 1)

ASSISTANT LECTURER (Grade III) or LECTURER (Grade II) in GEOGRAPHY—The Secretary, The University, Edmund Street, Birmingham 3, (June 2)

TECHNICAL ASSISTANT for Clinical Laboratory work (non-resident, female)—The General Superintendent, Royal Infirmary, Manchester BIOCHEMIST, preferably with some experience of INDUSTRIAL BACTERIOLOGY—The Director of Research, Linen Industry Research Association, Research Institute, Lambeg, Co Antrim, Northern Ireland

TEACHER (full-time) of MATHEMATICS—The Principal, Enfield Technical College, Queensway, Enfield, Middlesex

CHIEF ENGINEER to work in close collaboration with scientific staff in machinery development—The Director, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester 20

TECHNICAL RESEARCH IN A REHOUSING PROGRAMME

ON the national plane, the present period of great technical advance involves special difficulties which have been well illustrated in recent debates on the place of temporary and permanent houses in our building plans. It is clear that we must be ready to take full advantage of the many technical advances and of any improved methods of construction, but it is more than doubtful whether we are yet ready to decide which methods are likely to be most suitable for our various purposes. This is necessary not only to ensure efficiency, economy and speed in the development of our building programme, but also to ensure that our plans for raising and training a vast labour force take proper account of possible changes in building technique.

In his book "Re-building Britain—a Twenty Year Plan"*, Sir Ernest Simon sets out to delineate the conditions for outstanding success in a rebuilding programme, and, drawing upon his years of experience in Manchester and as an adviser to the Government, he gives a comprehensive survey of the possibilities and difficulties of rebuilding both houses and communities in Britain after the War. The book falls into two parts, dealing with housing and planning, respectively. The first includes a concise account of the achievements and shortcomings of the housing programme of 1919–39 and at the same time indicates the better preparations which have been made by the Government during the present War to organize the production of houses when hostilities cease. But while Sir Ernest brings together many facts and figures not easily obtainable and his book constitutes a useful reference work both in respect of planning and of building and housing, the treatment is somewhat uneven. It can scarcely be maintained that even within the limits he sets himself—Sir Ernest explicitly excludes the problems of the country, some aspects of the building industry, and the general aspect of the rent problem—he deals adequately with all the factors involved.

This reservation applies to many of the questions in which scientific workers themselves are more particularly interested. He notes, it is true, in his appreciation of the inter-war effort, that there was little or no research on the structure or fittings of the house, but his two chapters on technical planning and on prefabrication lay nothing like the stress on the importance of research which is given by Mr John Madge in "The Rehousing of Britain" in the Target for To-morrow Series†. Mr Madge points out, notably in a section on "The Gaps in our Knowledge", that energetic research is essential if we are to avoid one of the greatest dangers in the immediate post-war period. Without full knowledge of conditions and of new materials and building technique, we may waste time and effort upon second-rate solutions, even if reconstruction does not cut right across any integrated plan.

The greatest gaps are in the field surveys of the physical and economic conditions of our towns and regions, as was stressed by Mr E Carter in his paper on "Science and Housing" at the British Association Conference last January. If, in an attempt to alleviate the acute shortage which already exists and which will be accentuated by demobilization and the return of business offices to the towns, new housing and new office block schemes are rushed up in any space available before the new pattern has been determined, the future may be mortgaged to the immediate demand and the emergence of the new plan may be hampered for fifty years or more. This is the reason why it is so important to implement the social survey technique of obtaining housing information described by Dennis Chapman to the Agricultural Science Board in a paper appearing in the *Journal of the Royal Institute of British Architects* last year (51, 191, 1944), and in his paper on "Science and Housing" in the same journal, Mr A M Chitty shows the part which science has to play in developing the designs which will embody the results of such investigations, whether on the material plane, in securing effective economy of labour, of material and of time in the home, and on the social plane in relating the home to the proper working of the community as a whole.

While there is every indication, as both Mr Madge and Sir Ernest Simon recognize, that the Government is alive to the need for extended research in the technical field, it is less apparent that the bearing of such research on the labour situation is fully appreciated. Unless due attention is given to this aspect, however, we may find that after ten years or so we have a surplus of craftsmen trained in the traditional methods, and lack the skilled men we need to exploit modern processes. At present, as Mr Madge points out, the numbers proposed in the Government's plan for the traditional crafts appear to be over-liberal, and the allowance for current and prospective changes in building technique inadequate. Foresight, in fact, is as essential as energy in planning the housing drive, but without adequate research and experiment foresight is impossible. The changes in organization of the Ministry of Works and Building outlined by Mr Duncan Sandys in the House of Commons on March 23 may assist in repairing this defect, but only if the work of the separate department to undertake research and scientific development, of which Sir Reginald Stradling is to be the head, is effectively co-ordinated with the activities both of the Controller-General's department for building materials and building labour, and of the Director-General's department responsible for all building work, including factory production, transport, erection of temporary houses, etc.

So far as research into the properties and application of materials and techniques is concerned, the need for the future is for more research and, as Mr Madge insists, for research subordinated to the interests of the consumer rather than designed to push the products of any one firm or group of firms. Mr Chitty's paper demonstrates the need for more fundamental research, particularly in such fields as

thermal insulation and sound, ventilation and lighting, the prevention of moisture penetration, elimination of fire hazards, and the utilization of new materials so as to secure the requisite strength and stability, and the comparatively neglected problem of durability and maintenance, without attention to which decisions regarding obsolescence and a statutory life of buildings, for which Sir Ernest Simon calls, cannot well be made.

Leaving on one side the further question of service which also requires research and development, if the scientific worker is to design for high standards which can effectively be translated into the service of the needs of the mass of the people, the question of standardization becomes important. Mr Madge suggests that it should be possible for a member of the public to obtain official advice as to the quality of any particular building material or product, and restrictions should prevent any manufacturer from squandering national resources by investing labour and materials in unsatisfactory projects. The adoption of standards based on social and technical research, not merely for equipment but also in matters of space, permanence and amenity, would give a new positive basis to by-laws in place of the present restrictive system, and might go far to end the anarchic rule of jerry-building.

A scientific code of standards would also assist in securing the modification of those by-laws which based on the assumption that only traditional materials are to be used, have seriously retarded the development of legitimate new techniques and materials. Adoption of specification on a basis of performance standards would mean that each material or technique would stand or fall by the vigorous application of scientific tests. The efficiency of traditional building methods and of factory technique would thus be judged solely on their relative fitness for the purpose and would not be subject to irrelevant prejudice. The six-year programme suggested by Mr Madge, within which the temporary factory made house programme would be completed, would provide an opportunity for this testing, and the Building Requisites Board suggested by Sir Ernest Simon, taking over the responsibility for research and development from the Ministry of Works, should make a valuable contribution to this essential definition and adoption of standards where the Ministry might be less effective.

But this question of development leads us into other fields also. We have already seen its bearing on the effective use of the available labour supply by its contribution to personnel management and in securing the integration of management and workers through the works committees and in other ways, but there is a further aspect of even greater importance which is implied rather than discussed in a report on the interrelationship of architecture, engineering and the building and domestic equipment industries which has been prepared by Mr R Chapman and Mr R Perry at the request of the Engineering Industries Association. The sharing of housing among several industries, which is involved in factory production and the introduction of built-in equipment, is

robably the soundest means of dealing with the ultimate problem of contraction of the labour force which Sir Ernest Simon, for example, notably fails to discuss.

This report to the Engineering Industries Association declares that while the 'Portal house' has been evolved hastily to meet a political need without adequate research into the organizing, technical, economic and town-planning problems involved, it has opened the door to complete factory production and new technique. Based on an existing outline proposal, which by adequate research and development could readily and cheaply permit the evolution of a house without the defects of the Portal house, the report visualizes an annual target of 200,000 factory-made houses and 100,000 composite houses, partly additional and partly steel frames. Small research groups are suggested to carry out the initial experimental work, and the need for combining the technical and the economic approach is stressed.

The immediate need, according to this report, is for 2,000,000 building workers, and the long-term need for 800,000, both figures being spread over the additional building trades and the engineering industries. While the advantage of sharing building among several industries is undoubted, the absence of figures in the White Paper and elsewhere showing the relative costs of factory-produced houses built on additional lines in terms of man-hours, for example, makes it difficult to decide which method to adopt for the immediate programme. The debate in the House of Commons on March 22 and 23 established very clearly the crucial importance of the labour supply, and it is doubtful whether even for our short-term programme we can afford to adopt the factory-produced house if it makes bigger demands on manpower than traditional construction. On this point the admirable account of the demonstration houses and those erected at Northolt by the Ministry of Works* gives no more information than the White Paper.

Apart from Mr Horabin, speakers in the debate on housing paid little attention to research. Mr Horabin, however, stressing the fundamental importance of adequate housing research as a basis for the Government's programme—he is prepared to consider an expenditure of £7,000,000 for research—considers we have no adequate research in this field and urged that it is equally important to have the right people in charge of a department of housing research. They should be men of scientific standards, with engineering experience, and, besides technical research, we need statistical and consumer research. Statistical research is required to get an accurate, qualitative picture of the housing situation, and only through statistical and consumer research can we expect to arrive at the number of one-, two- and three-bedroom houses we require. Moreover, this co-ordinated research is required to reduce the number of man-hours on the site and to ensure that as much as possible of such work is done not only by craftsmen but also by selectors and assemblers.

Mr. Horabin recognizes the vital importance of efficient and enlightened management. Sir Ernest

Simon stresses this point also, it is necessary to secure the utmost economy of labour and the whole-hearted co-operation of the workers in the building industries. But it was left for Commander King-Hall to point out that part of the price to be paid for a solution of the housing problem is direction of labour and material, and much better control of land. Mr Madge in his book, like Sir Ernest Simon, recognizes the necessity of maintaining war-time controls over the costs and priorities of the building industry, and both books bring out this essential point that reconstruction must be within the framework of a national development pattern administered by a strong central planning authority. Rarely, however, is the fact faced frankly that labour, too, must accept restrictions, but it is essential, as Mr Buchanan pointed out in the House of Commons, that private and sectional interests should be seen to be subordinated to the interests of the nation as a whole. That is a first step, if we are to secure a much more helpful attitude than has yet been apparent in the building trade unions to the changes that are involved in pre-fabrication and other developments coming from building research.

"Rebuilding Britain", however, is not merely a compendium of facts, as indicated by its sub-title, Sir Ernest Simon sets out a definite plan, and this as well as its critical appraisal of the inter-war achievement and of the Government's weaknesses in dealing with the wider issues give additional interest to the book. In regard to the inter-war achievement, Sir Ernest points out that while it took fifteen years to work up to the building of 350,000 houses per annum in the national housing effort as a whole, an entirely new minimum standard of working-class houses was adopted. A second outstanding achievement, which no other great country has approached, was the building during 1919-39 of no less than four million new houses. These achievements should be remembered, although it is admitted that for financial reasons the houses tended to be too small, there was no adequate control over jerry-building, planning of the housing estates tended to be rigid and unimaginative, and the bigger questions of planning were scarcely considered.

Sir Ernest Simon's own twenty-year plan consists of three stages. The first, aiming at a house for every family, would take about five years, with the provision of 400,000 houses in each year from the fourth after the end of hostilities. In his estimate, however, he only provides for 50,000 in the first, and 100,000 in the second year, as against the 220,000 completed houses and 80,000 in course of erection of the Government's White Paper (Cmd 6609, H.M.S.O., 1945, 2d). The second stage aims at clearing the slums, with four million new houses to be built in ten years for slum clearance and four million cleared houses to be pulled down. This should be completed in sixteen years after the end of the War, and the third stage, involving the clearance and replacement of one million and a half obsolescent houses, should be complete in a further four years.

It may be argued that Sir Ernest deals too summarily with the question of scrapping houses and of

* Demonstration Houses. Pp 76 (London, H.M. Stationery Office, 1944) 1s net.

statutory life which PEP analysed last year in a broadsheet entitled "Old Houses". He does not allow in his estimate for the effect of a declining population upon demand, and he does not discuss at all the difficulty of contracting the labour force either on the completion of his twenty years plan or when the demand falls off under the influence of population changes and the altered obsolescence position. In his summary rejection of the Pole Report on "Private Enterprise Housing", he scarcely attempts to deal with the difficulties of sharing housing between municipal and private enterprise—his leaning to municipal housing makes him underestimate the difficulties, and he seems sometimes to forget that Manchester is scarcely a typical local authority and many local authorities have nothing like Manchester's resources or vision.

What Sir Ernest Simon does do in this book, especially in the last two parts, where he surveys first some foreign examples of planning and then the position in Britain, is to show how lamentably weak the Government's policy is in community planning, and how important the Government's failure to deal effectively with the question of the control of land in the national interest and the problem of compensation and betterment may yet prove to be. This is the second of the five conditions he lays down as essential for successful planning—the other four are suitable planning authorities—national, regional and local—adequate finance, proper national and local plans, and the necessary driving force to see that the job is done. But while he leans to national ownership as the only satisfactory solution of the land problem, he regards this as at present politically impracticable, and the examples he cites show what sound community planning can do without public ownership provided the planning powers are adequate.

Although Sir Ernest does not always answer the questions he raises, he puts the whole problem in a sound perspective and his book should assist in building up that intelligent public opinion which must supply the driving force in the successful rebuilding of Britain. The other two conditions are national prosperity and low rate of interest, and the book shows far more clearly than the White Paper how the housing question is related to the problem of full employment. Sir Ernest is optimistic. He recognizes the enthusiasm of the local authorities and the determination of many city councils to rebuild their cities on fine and imaginative lines. These, and the vigorous steps taken by the Government to ensure a strong building industry and to get to work quickly on housing after the War, are encouraging. If public opinion can bring the Government to take the major decisions of policy which are necessary to enable local authorities to go ahead with their planning, and if scientific workers see to it that research in regard to materials and methods at the technical level and the social level in regard to the needs of the home and of the community is prosecuted with vigour, with vision, and with adequate resources, there is no reason to doubt the ability of the country to seize the opportunity which is now arising in building, in housing and in planning.

THE FŒTAL CIRCULATION

The Foetal Circulation and Cardiovascular System and the Changes that they Undergo at Birth

By Dr Alfred E Barclay, Dr Kenneth J Franklin and Marjorie M L Prichard Pp xvi+275 (Oxford Blackwell's Scientific Publications, Ltd, 1944) 50s net

OF all the foetal systems, the cardiovascular has been the most provocative of theorizing. Its anatomy is linked with such names as Galen, Fallopius, Vesalius, Harvey, Lower, His, Born and Tandler in its physiology with Galen, Harvey, Méry, Wolf, Haller and Sabatier. As regards the experimental approach, Wilhelm Preyer's masterly work, "Speziell Physiologie des Embryo" (1885), still remain unique.

In this volume Barclay, Franklin and Prichard with due recognition of their Cambridge colleagues Barcroft and Barron, present an account of their combined work with emphasis on that part which has been the more direct concern of the Oxford team. The manner in which the problem has been approached and the technical details overcome will command the respect and admiration of all, for, as the authors state, "it consists of an account of our own foetal studies".

The first part, a historical survey, is followed by an account of the course of the blood through the foetal heart of the lamb as seen radiographically, including résumé of the technique and apparatus used. The third part deals with the anatomy and physiology of the circulation in the lamb foetus, and the neonatal changes. The comparative anatomy and physiology of the foetal cardiovascular system, mostly original work of the authors, constitute the fourth part of the book. Four chapters on the human cardiovascular system, with the speculations of the authors on the foetal circulation in man, form the fifth part of the volume, which concludes with a brief summary and anticipations of the period when the work may be extended to the human foetus.

The contributions of anatomists and physiologists from the time of Galen are recorded and assessed. Attention is again directed to the appropriation of the discovery of the ductus arteriosus and the foramen ovale (both known to Galen) by Botallo, and to the priority, often erroneously accorded to Arantius, for the discovery of the ductus venosus, already known to his teacher, Vesalius. Harvey's contribution is dealt with in great detail. Wolff's work receives recognition which it duly deserves. He undoubtedly had a clear idea of the anatomical relations of the channels in the foetal heart and obtained a more accurate insight into the foetal circulation than any of his predecessors. The technical errors of Kellogg and Pohlmann are discussed, together with the inaccuracies of their interpretations. Among the more recent experimental work on the foetal circulation the omission of that of Huggett is surprising. Indeed, his name does not appear in the whole volume. The authors credit Kellogg with the first experiments on the foetus delivered by Caesarean section, with the placental circulation intact and foetal respiration inhibited. Huggett's first paper on the tension of the blood gases in the foetus, with description of his technique, appeared in 1927 (*J. Physiol.*, 62), antedating Kellogg's first paper (1928 *Amer. J. Anat.*, not *Anat. Rec.*) by more than eighteen months.

Part 2 is devoted to the actual course of the blood in the foetal lamb as visualized by cine-radiography following the injection of opaque media into the circulation at various critical points. This part of the volume will undoubtedly receive the admiration of all who read it. The description, the twenty-eight figures and the four excellent frames of actual cinematographic records deserve the highest praise. It is the first depiction of the blood flow in the foetal circulation under conditions approximating to those within the amniotic cavity. The division of the post-caval blood stream on the annulus fossæ ovalis, which the authors prefer to call the crista dividens, is described.

In the chapter on the cardiovascular system of the lamb the authors introduce new functional terms for the older and more established anatomical ones. Whether this change of terminology should be adopted is doubtful. Physiological discoveries must undoubtedly call for a constant revision and extension of terminology, but the term introduced must also be acceptable to those seeking to explain the mechanisms of morphological changes in the embryo and foetus. For example, the authors suggest the name 'umbilical venæ comites' for the paired umbilical veins in the cord, as distinct from umbilical vein or the unpaired structure within the abdomen. The evolution of right and left umbilical veins, primarily paired veins, is disregarded here. In the marsupials, McClure has named the fused umbilical veins within the abdomen the umbilical sinus. Umbilical venæ comites seems scarcely justifiable. On the grounds of priority, the authors dissociate the name of Arantius from the term ductus venosus. The particular channel so admirably described by Arantius in the human and its homologue in other mammals must be distinguished from other channels similarly named. Tribe, in her paper on the hepatic venous system, gives a translation by Thane of the original description by Arantius: "So that if you introduce a probe into the umbilical vein you will arrive in the trunk of the portal vein and then by means of the said communication (*the ductus venosus*) straight into the vena cava." Hill and Tribe prefer to retain the term ductus venosus Arantii for this type of channel, and to use the unqualified term ductus venosus for the channel connecting the vitelline vein with the postcaval vein. There is some justification for retaining the name of Arantius for this type of ductus venosus, if only by virtue of the clarity of the original description in 1564.

The comparative studies dealt with in Part 4 are fragmentary, but extremely valuable and stimulating. Discussion of the placenta is brief and follows the lines of Grosser's classification, the only one of value to both physiologist and embryologist. In many ways the sheep's placenta, despite the classical work of Assheton on the ungulate placenta, may still be termed, like the spleen, *organon plenum mysterium*.

The umbilical cord, despite its apparent simplicity, affords many unsolved problems. Of the smaller blood vessels in the stroma of the cord, the authors say little, and have omitted the observations of Wislocki, who credits Klaatsch with the first description of these vessels. It would appear that man and primates have an avascular stroma, while other mammals possess a capillary plexus. Except for its most proximal segment, capillary channels occur in the primate cord only during the early stages of formation of the paired umbilical arteries and veins. The authors consider that the vessels can scarcely be

the vasa vasorum of the umbilical vessels, but do not mention Wislocki's view that they may be the vasa propria of the stroma. Of the blood vessels in the proximal portion of the human cord, they have little to add to that already written, but it is obvious that little is known of the nutrition of the umbilical cord, of the vascular plexus in the proximal segment of the human cord, or of the para-umbilical veins. Of the strength and site of rupture of the cord, it is doubtful if many would subscribe to the views of Shordania, for the site of rupture in the human is generally at or close to the umbilicus. The irritability of the umbilical vessels and their 'valves' are adequately considered so far as existing knowledge permits. One of the valuable features of this section of the book is that attention is forcibly directed to the series of unsolved problems in so simple an organ as the cord.

The territorial distribution of the umbilical and portal veins in the liver during foetal life follows Mall's classical work on the liver lobule and the rather wider approach of Charnock Bradley. It is difficult to correlate the work that has been done on this aspect of the foetal liver. It is surprising that the work of Bonne (1904) has not received the attention of the authors, since this was done on the foetal liver in sheep and his results closely resemble theirs.

The tissue surrounding the 'sphincter' on the ductus venosus is described as 'oedematous'. This word implies a pathological state. The oedematous tissue is the normal loose areolar tissue of the type seen near contractile and expansile organs.

In the light of the authors' radiographic work, their 'via sinistra' (valve of foramen ovale) and 'via dextra' (right moiety of the postcaval channel) are carefully described in sheep and man. Little seems to be known of the functional closure of the via sinistra or of the ductus arteriosus, other than that provided by the work of this team.

The neonatal and postnatal changes in these transient channels have been studied microscopically by many anatomists, but the authors rightly omit these. Observations on the onset of respiration in sheep are discussed with reference to Barcroft's views. Huggett's prior observations on respiration following delivery of the goat foetus are omitted. The statements about parturition in captive animals are not enlightening. Our knowledge of parturition in primates is meagre, but the position is being clarified by Elder and Yerkes in chimpanzees and by Hartmann in the macaque, reference to whom has been omitted. Of the actual time of birth the authors state, "Almost all primate births occur at night." Elder and Yerkes state the opposite. Concerning placentophagia in the primates, the experience of Dr Ververs quoted here seems to be at variance with that of Hartmann and Elder and Yerkes. Hartmann states, "all deciduate mammals except man if left to themselves will eat the afterbirth and this holds for the herbivores." In the one series of chimpanzee births recorded by Elder and Yerkes, seventeen out of twenty-nine ate all or part of the placenta. They state that under natural conditions the percentage of placentophagia would probably have been considerably higher.

In Part 5 the authors attempt "to know better what happens in the human subject." In applying their results in sheep to the human, they have been justifiably cautious but effective. There is much support for the view that the circulation in the human is not dissimilar to that in the sheep. They

look to the time when more direct evidence of the changes occurring at birth in the human cardiovascular system will be available

The foregoing criticisms must not be allowed to detract from the value of this publication. It is full of information and is the most comprehensive and satisfying account in existence of the foetal circulation and its neonatal changes. The work done by this team should command the admiration of all interested in the young mammal. The gaps in our knowledge are clearly enunciated and should act as a stimulus to embryologists, obstetricians and physiologists alike. The numerous illustrations are of high quality, the bibliography and index most useful. The authors, publishers and the Nuffield Institute for Medical Research alike deserve credit and thanks for producing so monumental a treatise in war-time.

D V DAVIES

TRAVELS OF A BOTANIST

A Life of Travels

By C S Rafinesque. Being a verbatim and literatim reprint of the original and only edition (Philadelphia, 1836). Foreword by Elmer D Merrill, Critical Index by Francis W Pennell (Chronica Botanica, Vol 8, No 2). Pp 291-360+plates 5-8 (Waltham, Mass Chronica Botanica Company, London Wm Dawson and Sons, Ltd, 1944) 2 50 dollars

RAFINESQUE was a peculiar character who, in the course of a vagrant life of fifty-seven years, worked according to himself as "a Botanist, Naturalist, Geologist, Geographer, Historian, Poet, Philosopher, Philologist, Economist and Philanthropist". But primarily he was a plant taxonomist, whose work Dr Merrill suggests in the foreword to this volume, has not received the attention that it deserves.

Rafinesque was born "at Galata, a suburb of Constantinople", in 1783, and died in Philadelphia in 1840. With the exception of a period of ten years in Sicily, most of his adult life was spent in America. He was apparently an indefatigable traveller, who made long laborious journeys "by nearly all the possible manners except by camels and in balloons". He was also an extremely zealous collector, so much so that of one episode he writes "In wading through Green R. I narrowly escaped drowning, but collected many fine shells". In the intervals between the successive journeys he led a busy life writing books, maintaining an elaborate correspondence with many of the leading naturalists of his day, and earning his living. Unfortunately in this last undertaking he was not very successful. On one occasion some of his collections "remained for a while in store and under a mortgage", and repeatedly in the account of his travels he complains of the duplicity of those who would not recognize his just financial claims. At one time he earned his living as a teacher of Italian, drawing and botany, later he was appointed to a "Professorship of Botany and Natural history, with the addition of modern languages, with lodgings, boarding and casual emoluments", and later still he became "a Pulmist, who attended only to the diseases of the lungs, as a Dentist attends only to the teeth". And again towards the end of his life he became "the Actuary" for an institution that was born of his own ingenuity, "The Divital Institution and six per cent Savings Bank".

These details are given in "A Life of Travels", which was first published in Philadelphia in 1836,

and which has now been reprinted in this edition. The passages in which they are recorded, however, are only occasional interpolations in an arid recital of places visited and routes followed. Throughout there is little description either of the observations or of the collections made during the several journeys. There are a few incidental comments, but these are not expressed with any particular originality. For example, of himself, Rafinesque writes "I never was happier than when alone in the woods, or resting near a limpid stream or spring, I enjoyed without contro the gifts of Flora, and the beauties of Nature". Nevertheless, the journeys that are described in such minute detail are of considerable interest in relation to the taxonomic work that was based on them, and to that extent the publication of the present volume is fully justified. Evidently this edition has been prepared with considerable care, but since itineraries are a prominent feature of the text, the value of any future edition would be considerably enhanced by the provision of illustrative maps, of which there is none in this.

R BROWN

PHOTOGRAPHY OF THE RECIPROCAL LATTICE

The Photography of the Reciprocal Lattice

By M J Buerger (ASXRED Monograph No 1 published by the American Society for X-Ray and Electron Diffraction). Pp ix+37 (Cambridge Mass Murray Printing Co, 1944) 1 50 dollars

NOT many years ago an account of single-crystal X-ray diffraction methods would have been considered complete if it had referred only to the Laue, rotation and oscillation methods, with particular emphasis on the last. There might also have been some mention of moving-film methods, such as the Weissenberg. All this is now changed. Moving film methods bid fair to displace other methods completely, even for the study of polycrystalline aggregates.

Prof Buerger's book adds another chapter to the use of these methods, he has been able to devise apparatus whereby sections of the reciprocal lattice—the representation of the diffraction pattern of a crystal—can be obtained without distortion. In other words, the indices of the X-ray reflexions can be read off without the use of charts, with a consequent saving of time and an increase in reliability.

The book gives full details of the theory of the apparatus and contains several beautiful examples of photographs taken with its use. The author also gives a very fair estimate of the advantages and disadvantages compared with other methods. In particular, it will not give part of the reciprocal lattice near the origin, in common with all methods except the equi-inclination Weissenberg.

There are a few criticisms that can be made. The author claims that the method is inherently more accurate than most other moving-film methods, but he does not give a clear statement of the accuracy that can be expected from it. Also the title of the book is misleading, all methods that use characteristic radiation give a representation of the reciprocal lattice. These, however, are small points, and the American Society for X-Ray and Electron Diffraction is to be congratulated on the first of the monograph it has produced.

H LIPSON

PLANT-GROWTH SUBSTANCES AS SELECTIVE WEED-KILLERS

Differential Effect of Plant-Growth Substances on Plant Species

STUDIES of the effect of growth substances upon plants began at Jealott's Hill Research Station in 1936. The earliest work dealt with the stimulation of the rooting of cuttings and it was extended to discover the effect of ranges of concentrations of 3-indolylacetic acid and α -naphthylacetic acid upon seed germination, upon seedling growth and upon the growth of established plants of many species. The results of these experiments have already been reported^{1,2}, and in them it was observed that the higher concentrations of growth substance depressed growth. This observation, together with our knowledge of the variation of the extent of rooting and deformative effects produced in the different species, led us to expect that these growth substances in higher concentrations would show a selective phytocidal action. We found in August 1940 that applications at the rate of 15 lb of α -naphthylacetic acid per acre to oats (*Avena sativa* L.) weedy with yellow charlock (*Brassica sinapis* Visianii) killed the charlock. The oats only received a slight setback and recovered fully. The application was made just after seed-sowing time. 4 per cent of the charlock failed to germinate, and those seedlings which did emerge afterwards died. Several experiments in soil and sand and upon filter paper in the laboratory confirmed these results and indicated that wheat, barley and rye behaved similarly to oats, while greater plantain (*Plantago major* L.) and yarrow (*Achillea millefolium* L.) were like yellow charlock in their responses.

Thus, we had confirmed our expectation of selective phytocidal action of certain growth substances, for indolylacetic acid and α -naphthylacetic acid killed some major weeds in cereal crops without harming the cereals, wheat, oats and barley. We followed up this lead by experimenting with other growth substances. For if growth substances were to be of use to the farmer as selective weed-killers, it was necessary to find one which was cheaper than or much more active than α -naphthylacetic acid. We already knew plant-growth action was not characterized by a close degree of correlation with chemical constitution, and consequently we made a chemical survey of known growth substances and substances structurally related to them. Substituted phenoxyacetic acids and naphthoxyacetic acids were found to be outstanding and certain of them were found to be fifty times as active as α -naphthylacetic acid. The following list shows some of the compounds tested.

Class A Activity greater than α -naphthylacetic acid

o-methyl-phenoxyacetic acid (Na salt)
m-methyl-phenoxyacetic acid
p-methyl-phenoxyacetic acid
2,4-dimethyl-phenoxyacetic acid
2,5-dimethyl-phenoxyacetic acid
3,4-dimethyl-phenoxyacetic acid
p-chloro-phenoxyacetic acid (Na salt)
2,4-dichloro-phenoxyacetic acid
2,5-dichloro-phenoxyacetic acid
4-chloro-2-methyl-phenoxyacetic acid
4-chloro-3-methyl-phenoxyacetic acid
 β -naphthoxyacetic acid (Na salt)
2,4-dichloro- β -naphthoxyacetic acid (Na salt)
methyl- β -naphthoxyacetate
propyl(n)- β -naphthoxyacetate
propyl(iso)- β -naphthoxyacetate
butyl(iso)- β -naphthoxyacetate

Class B Activity approximately equal to α -naphthylacetic acid

o-chloro-phenoxyacetic acid (Na salt)
2,4,6-trichloro-phenoxyacetic acid (Na salt)
ar-tetrahydro- β -naphthoxyacetic acid
 β -naphthoxyacetamide
 β -naphthoxyacetonitrile
ethyl- β -naphthoxyacetate
butyl(n)- β -naphthoxyacetate
cyclohexyl- β -naphthoxyacetate

Class C Some activity

phenoxyacetic acid
p-nitro-phenoxyacetic acid (Na salt)
2,4-dinitro-phenoxyacetic acid (Na salt)
 α -naphthoxyacetic acid (Na salt)
1-chloro-2-naphthoxyacetic acid (Na salt)
2-chloro-1-naphthoxyacetic acid (Na salt)
ethyl- α -naphthoxyacetate

Experiments carried out in November 1941 showed that 4-chloro-2-methyl-phenoxyacetic acid was one of the most active compounds tested, and that it readily depressed the germination and early seedling growth of corn buttercup (*Ranunculus arvensis* L.), fat hen (*Chenopodium album* L.), corn marigold (*Chrysanthemum segetum* L.), corn spurrey (*Spergula arvensis* L.) and field poppy (*Papaver Rhoeas* L.) at concentrations which were without effect on cereals. Pot and field experiments showed that germination of yellow charlock was suppressed and plants at any stage from seedling to flowering were readily killed by spraying with solutions of sodium 4-chloro-2-methyl-phenoxyacetate supplying only 10 mgm per square foot (equivalent to approximately 1 lb per acre) of active principle. The affected plants showed marked epinasty and died slowly. The substance appears to persist in the soil for several weeks. Work is at present in progress to extend our knowledge of this effect and to gather information on the underlying causes. In view of the very low concentrations of these substances which bring about such marked differences, it is possible that such materials present or produced in soils may have big influences on the nature and composition of the plant associations growing upon them.

In November 1942 we communicated all our knowledge on selective weed-killers to the late Dr W. C. Topley, secretary of the Agricultural Research Council, and from that date we have co-operated with Dr J. H. Quastel, Dr H. G. Thornton, Dr P. S. Nuttman and Mr G. E. Blackman.

In 1943 a field trial showed that sodium 4-chloro-2-methyl-phenoxyacetate applied at 1 lb/acre gave 100 per cent eradication of yellow charlock in spring oats without damaging the cereal, and equally good results were obtained if application was made when the weeds were small or when they were in full flower.

We carried out a further programme of field experiments in 1944 which have confirmed and amplified the earlier results. Yellow charlock (*Brassica Sinapis Visianii*), white charlock (*Raphanus Raphanistrum* L.), corn buttercup (*Ranunculus arvensis* L.) and pennycress (*Thlaspi arvense* L.) have all been eradicated from cereal crops by 1 lb/acre applied as a spray in 100 gallons/acre of water. If the application was made in a dry form using china clay as a diluent, 2 lb/acre of active principle gave similar results with these weeds. There are differences in the sensitivity of weeds, for example, mayweed (*Anthemis Cotula* L.) appears to be somewhat resistant. It is evident that sodium 4-chloro-2-methyl-phenoxyacetate is effective whether absorbed through the root or leaf of the weed and can be used to prevent seed germination of the weeds specified above as well as to destroy established plants. This material is also non-corrosive. Further research is being done

to elucidate the usefulness of this material for a variety of weeds and crops

Full details of this work are being published elsewhere

Suggestions that synthetic growth substances might be used as selective weed-killers have been made recently and independently by Beal³, Mitchell and Hamner⁴ and by Hamner and Tukey⁵

Inhibition of Plant Growth by 2:4-Dichlorophenoxyacetic Acid and other Plant-Growth Substances

THE work on this subject began at Rothamsted in November 1941 as a result of the previous study of the deformation of legume root hairs made by H. K. Chen, which indicated that the curling of root hairs by *Rhizobium* was due to the secretion by the latter of β -indolylacetic acid. Our first experiments were intended to discover whether a similar deformation of root hairs could be induced by β -indolylacetic acid itself and by related plant stimulants

In these and in subsequent experiments, where agar was used, a basal medium was employed having the following percentage composition: K_2HPO_4 , 0.05, KH_2PO_4 , 0.05, $Ca_3(PO_4)_2$, 2.0, $FePO_4$, 0.5, $MgSO_4 \cdot 7H_2O$, 0.02, $NaCl$, 0.01, $FeCl_3$, 0.001, KNO_3 , 0.1, agar, 1.5. This medium was put up in test tubes, sterilized, and appropriate dilutions of the compounds to be tested were separately sterilized and added aseptically to the melted medium. Slopes were then made and two seeds of the test plant, externally sterilized by successive immersion in 80 per cent alcohol and 0.2 per cent mercuric chloride and washed in sterile water, were placed at the top of the slope in each tube.

In our early experiments we found that β -indolylacetic acid and α -naphthylacetic acid both produced marked root-hair deformation in the agar cultures of red clover, in the absence of *Rhizobium*. But it was also found that both compounds were toxic to germination and to subsequent growth at dilutions up to 1 in 10,000,000. Results of a typical experiment are given in Table 1.

In view of the possibility that tryptophane may be the parent source of β -indolylacetic acid produced by *Rhizobium*, the toxic action of tryptophane itself was tested. Results showed that, in sterile agar medium, tryptophane exerted a toxic action to red clover at concentrations of more than 10 parts per million, but that where *Rhizobium* was also present, the limit of toxicity was lowered to 1 part per million. These results support Thimann's¹ and Chen's² evidence, indicating that this organism is able to produce β -indolylacetic acid from tryptophane.

TABLE 1 TOXIC ACTION OF GROWTH SUBSTANCES ON RED CLOVER

Compound	Concentration in p.p.m.	Total seeds sown	Germination affected	Subsequent growth affected	Normal seedlings
β -Indolylacetic acid	100	15	15	0	0
	10	15	12	2	1
	1	15	8	4	5
	0.1	12	0	11	1
α -Naphthylacetic acid	100	15	15	0	0
	10	15	15	0	0
	1	15	5	9	1
	0.1	15	4	8	3
Control	0	15	2	0	13

The high toxicity of β -indolylacetic acid and α -naphthylacetic acid suggested the possibility of using such compounds for controlling plant-growth. We therefore made an experiment to determine whether the above compounds were equally toxic to other plants and whether toxicity was affected by conditions in soil. In this experiment we tested the two compounds at 10, 1 and 0.1 parts per million in the agar medium, or the soil solution, on red clover, lucerne, and mustard, and, in addition, β -indolylacetic acid on wheat. We made the tests in agar medium and in unsterilized Rothamsted soil. In the agar medium, β -indolylacetic acid was toxic to clover and lucerne at concentrations down to 0.1 part per million, and to mustard to 1 part per million, whereas wheat was affected only at 10 parts per million. α -Naphthylacetic acid was toxic to clover and lucerne at 0.1 part per million and to mustard at 1 part per million. In unsterilized soil, however, neither compound showed any toxicity except at the highest concentration of 10 parts per million, where there was a slight effect. A further experiment showed that the toxicity of β -indolylacetic acid remained in sterile soil though its loss in unsterilized soil was confirmed.

We concluded that neither compound would be of practical use for controlling plant growth in natural soil owing to the loss of its toxic action, probably through decomposition by soil micro-organisms. We therefore sought for a molecule of comparable toxicity, less liable to microbial attack. In view of the known activities of phenoxyacetic acids as plant stimulants, and the likelihood that chlorinate compounds would be resistant to bacterial action, we decided to investigate the comparative toxicity in agar and in unsterilized soil of 2:4-dichlorophenoxyacetic acid. We therefore made tests, in October 1942, on red clover, using 2:4-dichlorophenoxyacetic acid as well as the related compounds α -naphthoxyacetic acid and the methyl esters of α - and β -naphthyl

TABLE 2 EFFECTS OF VARIOUS COMPOUNDS ON ROOT LENGTH IN OM RED CLOVER IN AGAR AND IN WOBURN SOIL

Compound	Concentration in p.p.m. of the agar medium and the soil solution			
	in agar		in soil	
	1	100	1	100
α -Naphthylacetic acid	7.7	2.4	—	5.2
2,4-Dichlorophenoxyacetic acid	1.1	0.6	2.0	0.3
Methyl ester of α -naphthoxyacetic acid	7.2	0.3	—	6.7
Methyl ester of β -naphthoxyacetic acid	5.7	2.1	8.0	3.6
Methyl ester of phenoxyacetic acid	5.6	7.1	—	7.9
Control	7.9		6.8	

xyacetic acids and phenoxyacetic acid, the last three compounds being included to test the effect of esterification. The results are given in Table 2.

4-Dichlorophenoxyacetic acid was much the most toxic of the compounds tested and, unlike the others, retained its toxicity to a satisfactory extent in sterilized soil. We also noticed that its action, though affecting germination and top growth, showed most strikingly in its stunting effect on root growth. We therefore took root-length as a measure of toxicity.

The action of 2,4-dichlorophenoxyacetic acid in sterilized soils of two widely different types and towards different types of plant was then tested. The test was made on red clover, sugar beet and wheat in test-tubes containing (1) Woburn soil, a light sand low in organic matter, and (2) Rothamsted allotment soil, a clay loam rich in organic matter. The clover was also tested in the agar medium. The 2,4-dichlorophenoxyacetic acid was added in concentrations giving 1 to 100 parts per million in the soil solution. The diagram above shows the relative mean root-lengths from nine replicates, after four weeks growth, expressed as percentages of those in control plants. In Woburn soil 2,4-dichlorophenoxyacetic acid was strongly toxic to clover and especially to sugar beet, even at 1 part per million. Wheat, however, was not appreciably affected at the lower concentrations, though marked toxicity appeared at 10 parts per

million. In the Rothamsted soil, toxicity towards clover and wheat was less marked, although the action on sugar beet was again very striking. In this soil also, wheat was the least affected of the three plants. In a further test on Woburn soil, we found that the addition of 0.1 per cent of potassium nitrate had no effect on the toxicity of 2,4-dichlorophenoxyacetic acid over the same range of concentrations.

We then tested the persistence of the toxicity of 2,4-dichlorophenoxyacetic acid in unsterilized soil. The compound was added to Woburn soil in test tubes, at concentrations of 1, 10 and 100 parts per million of the soil solution with untreated controls. These tubes were stored for thirty-six days, after which a second set of tubes with similar treatments was set up and both sets were then sown with red clover. Table 3 shows the mean root-lengths (from nine replicates) after four weeks growth. The usual toxicity was shown in the tubes sown immediately after adding 2,4-dichlorophenoxyacetic acid, but storage had completely removed the toxicity.

The action of leaching on 2,4-dichlorophenoxyacetic acid in Rothamsted allotment soil was then tested. Air-dry soil was put up in two sets of 10 cm. glass pots. One set was allowed to take up water and the second a solution of 10 parts per million of 2,4-dichlorophenoxyacetic acid, up to saturation capacity. During the following three days, pots of each set were given 2, 4 and 8 successive leachings, equivalent respectively to the slow percolation at 1.4, 2.8 and 5.6 in. of water. Control unleached pots of each set were kept. After the leachings, the surface of each pot was sown with clover, sugar beet and wheat, and the pots were then normally watered. The results of this test showed that leaching equivalent to 1.4 in. of water produced a reduction in toxicity that was just significant, while even that equivalent to 5.6 in. failed to remove all the toxic effect.

Discussion. The action of 2,4-dichlorophenoxyacetic acid on the plant varies according to concentration from complete inhibition of germination to a stunting of the root system and dwarfing of the leaves. This effect on the roots is accompanied by a marked thickening of the cortex and also, in certain cases, by the development of numerous short laterals. The formative effects noted by Zimmerman and Hitchcock³ were also shown in clover chiefly by the multiplication and displacement of the leaflets and by inflation of the petiole. The macroscopic symptoms were similar to those produced by β -indolyl- and α -naphthylacetic acids.

Problems of great physiological interest are raised by the fact that these compounds, which are known to stimulate extension growth and to have profound developmental effects, are also toxic to the whole plant in doses of 0.1–1.0 part per million. 2,4-Dichlorophenoxyacetic acid, however, differs from such compounds as β -indolyl- and α -naphthylacetic acids in that it persists long enough in unsterilized soil to produce marked toxic effects. These effects show at a concentration of 1 part per million of soil solution, equivalent to 1 part in 4 millions of soil at 25 per cent moisture, representing on a field-scale about $\frac{1}{2}$ lb. per acre of soil to 6 in. depth. It would thus seem that this compound should be of use in controlling plant-growth. It is not readily leached from soil but yet possesses the advantage of ultimately losing its toxicity, thus it would be unlikely to poison the land. The fact that

TABLE 3. TOXICITY OF 2,4-DICHLOROPHENOXYACETIC ACID TO RED CLOVER WHEN SOWN IMMEDIATELY, AND AFTER 36 DAYS FROM TIME OF ADDING THE COMPOUND TO UNSTERILIZED WOBURN SOIL.

Concentration in p.p.m. of soil solution	Seedling root-length (cm.)	
	Sown immediately after addition of compound to soil	Sown 36 days after addition of compound to soil
100	0.0	8.2
10	0.0	8.5
1	3.8	8.4
Control 0	7.6	8.3

different types of plants vary greatly in susceptibility to its toxic action may here be of considerable practical importance

A. Comparison of Certain Plant-Growth Substances with other Selective Herbicides

With grants from the Agricultural Research Council, a research team at the Imperial College of Science and Technology has been engaged in studying the general problem of weed eradication by chemical methods. Since April 1943, 4-chloro-2-methyl-phenoxyacetic acid and 2,4-dichlorophenoxyacetic acid have been included in the investigations. Their performance under field conditions has been compared with other herbicides in some forty-eight experiments involving more than 3,000 plots.

Special attention has been given to the control of annual weeds in cereal crops. In particular, a comparison has been made of the two phenoxyacetic acid derivatives with copper chloride, sulphuric acid and either a suspension of dinitro-*ortho*-cresol or a solution of the ammonium salt. When the spray concentrations—at the standard rate of 100 gallons per acre—are kept within the limits at which each herbicide is truly 'selective', then a feature of the results is the specific action of the several herbicides on different weed species.

The reactions of the chief annual weeds investigated are summarized in the accompanying table. It is seen that whereas for some weeds such as *Brassica arvensis* or *Thlaspi arvense* several herbicides are capable of giving a high degree of control, for other species like *Scandix Pecten-Veneris* or *Matricaria inodora* one compound is alone effective. Moreover, copper chloride and sodium 4-chloro-2-methyl-phenoxyacetate are more specific than dinitro-*ortho*-cresol in the narrower range of weeds they can destroy or partially control.

Following on weed suppression, increases in the yield of grain up to 90 per cent have been recorded. There is no indication that dinitro-*ortho*-cresol at the concentrations required for weed control (0.3–1.2 per cent) has checked growth. Both copper chloride at the higher concentrations (3–4 per cent) and sulphuric acid (9–18 per cent) have given smaller increases in yield. 4-chloro-2-methyl-phenoxyacetic acid, over a range of 0.025–0.25 per cent, has no adverse effect on spring- and autumn-sown cereals, but at higher concentrations it may cause a reduction in yield of spring oats and barley. The evidence to date is that 2,4-dichlorophenoxyacetic acid is less selective in its action and is more likely to injure the crop.

The phenoxyacetic acid derivatives are outstanding in that they can operate through absorption by both the shoot or the root. In consequence, germination of weed seedlings in the soil may be suppressed for some weeks after application. The suppression of

* Brackets indicate that category is tentative

B. arvensis and *E. cheiranthoides* has been obtained with amounts of 0.5–1.0 lb per acre, but for other species, such as *Polygonum Persicaria* (willow weed), there is no inhibiting effect. The minimal quantity required to kill susceptible weeds, once they have emerged through the soil, is less—an almost complete control of *B. arvensis* has been obtained at a spray concentration equivalent to 4 oz. per acre of the sodium salt.

In addition to the investigation of cereal crops, the research has been extended to cover annual weed control in grasses, clovers, etc., for seed production in flax and linseed, peas, onions, leeks, and perennial weeds in grassland. With grasses, once the seedling stage is passed, sulphuric acid, cupric chloride, dinitro-*ortho*-cresol and 4-chloro-2-methyl-phenoxyacetic acid can be employed for the destruction of annual weeds. The clovers in the early stages are either killed or severely checked by such spray treatments, though they are somewhat more resistant when fully established.

In flax, copper chloride and the sodium salt of dinitro-*ortho*-cresol have given the most promising results. The ammonium salt causes serious crop injury. 4-chloro-2-methyl-phenoxyacetic acid, although it may in no way affect the straw or seed yield of flax, will bring about a reduction in fibre yield. The extent of the reduction is dependent on the concentration and the time of spraying. Only sulphuric acid and cupric chloride can be employed in onion and leek crops for selective weed control. Dinitro-*ortho*-cresol compounds and the phenoxy

acetic acid derivatives are toxic. Preliminary trials suggest that maize is resistant to some dinitro-*ortho*-cresol compounds, and 4-chloro-2-methyl-phenoxy-acetic acid.

The phenoxyacetic acid derivatives are again exceptional in that they alone show promise for the control of some perennial weeds. In established grassland the experiments indicate that 4-chloro-2-methyl-phenoxyacetic acid, at concentrations which do not kill out *Trifolium repens*, from a single spraying, will destroy buttercups (*Ranunculus* spp.), *Equisetum arvense* (horsetail) and partially suppress *Cirsium arvense* (creeping thistle). At these levels of concentrations—up to 2.5 lb. per acre—*Rumex* spp. (docks), *Urtica dioica* (stinging nettle) and *Pteris aquilina* (bracken) are resistant.

The following members of the team have taken part in these investigations: A. J. Rutter, J. Carpenter, H. Wild, B. G. Goodey, J. L. Crosby, C. P. Whittingham, P. A. Tallentire, A. C. Crundwell, P. Greig-Smith, J. C. Gimingham.

ARTIFICIAL PROTEIN FIBRES: THEIR CONCEPTION AND PREPARATION

By DR. W. T. ASTEURY, F.R.S.

Textile Physics Laboratory, University of Leeds

A PRINCIPAL aim of science in relation to industry is to elucidate for the industrialist the nature of his working materials. All fundamental research into the structure and properties of things is therefore of potential value to industry; but this is a platitude to the man of science. To the non-scientific majority, however, it is not yet so obvious, and it is still regrettably necessary to make play with the more spectacular discoveries in order to attract proper support for research.

A recent development that has captured the imagination of the public is the discovery how to make artificial protein fibres from nuts, beans, milk, and other not visibly fibrous protein sources, and the official announcement during December 1944 by Imperial Chemical Industries, Ltd., of the successful production of 'Ardil' from the protein of pea-nuts suggests an occasion for briefly re-telling the story, but this time more from the fundamental point of view than has been possible in the popular accounts that have appeared. I have no intention here of labouring the theme of what industry owes to science, or vice versa, or of emphasizing again that the great industries of the future must draw their sustenance from unremitting research; but I would certainly like to stress the case of the artificial protein fibres as being a most impressive example of the indivisibility of science. The discovery of the underlying principles was of purely academic origin, an outcome of X-ray and related studies of the molecular structure of biological tissues—studies that were neither supported by nor consciously dedicated to industry; the basic experiments were compounded of physics, chemistry, and biology, and were carried out in a university. Thereafter the development to com-

mercial satisfaction was the work of industrial chemists and technologists.

It is not claimed, of course, that artificial protein fibres had never been produced previously—indeed, it happens that the casein fibre, 'Lanital', for example, was launched in Italy at almost the same time as the quite independent fundamental investigations about to be described were pointing the way to the general solution of the problem—but it is clear that in the absence of any structural picture of the protein molecule, and especially of the relation between the fibrous and the non-fibrous proteins, all such ventures were necessarily along empirical lines. The difference now is that what industry there was has been re-born as an inseparable part of protein science, with all the potentialities for advancement that this profoundest of molecular studies has to offer. It is in fact a logical prediction from the X-ray interpretation of protein denaturation that it should be possible to make fibrous from non-fibrous proteins; we can see now both what has to be done and the reason for it.

Since the beginning of the century, chemists have been increasingly convinced that all proteins are polypeptide chain systems, alone or in combination with various prosthetic groups; but there seemed to be a distinction between the fibrous and non-fibrous kinds in that the molecules of the latter are massive, rounded bodies that often aggregate to build orthodox, visible crystals; hence the name 'corpuscular' proteins. With the growth of the concept of fibres as 'molecular yarns' constructed from long chain-molecules, a concept to which many techniques have contributed but which first became 'real' under the methods of X-ray analysis, there ceased to be any formal difficulty with regard to the protein fibres, as was demonstrated by Meyer and Mark when, in 1928, they interpreted the diffraction pattern given by natural silk (fibroin¹); but the problem of the arrangement inside the corpuscular proteins remained, for sometimes the X-ray photographs showed sharp reflexions—characteristic to be sure of regular crystal lattices but not to be carried much beyond that on account of the large number of atomic parameters involved—but more often they showed simply two diffuse rings of spacing about 9½ Å. and 4½ Å., respectively. The first requirement was to explain these two rings, and this was done² on the basis of the X-ray data given by the elastic fibrous protein, keratin. Keratin did not fit in with the idea of extended polypeptide chains that had been found to suffice for fibroin; only the stretched form (β-keratin) could be interpreted on such a view, but the normal, unstretched form (α-keratin) demanded the postulate of a regularly folded configuration besides. The reversible intramolecular transformation between α- and β-keratin, corresponding to the transition between two distinct types of diffraction pattern, was recognized as providing the explanation of the well-known long-range elasticity of mammalian hairs and other keratinous tissues³.

Among other things, then, the X-ray study of keratin brought out the two main points from which in due course the theory of artificial protein fibres followed naturally. The α-form revealed for the first time the existence of polypeptide chains that are normally in a folded state, while the β-form gave the average dimensions per amino-acid residue (and therewith an estimate of the order of density of proteins and the mass per unit area of protein monolayers^{2,4}), and so bridged the gap to analytical chemistry and laid the foundations of a structural

Fig. 1. X-RAY POWDER PHOTOGRAPHS OF (a) DRIED EGG WHITE, AND (b) DRIED BOILED EGG WHITE.

stoichiometry⁵. Thus was evolved the concept of the 'polypeptide grid', and the two rings so common in protein diffraction patterns were identified as arising from the two principal modes of linkage between neighbouring polypeptide chains, namely, that between the side-chains and that between the backbones². The corresponding spacings are now always referred to as the 'side-chain' and 'backbone' spacings.

The next advance came from an X-ray comparison of a number of protein preparations before and after wetting⁶. It was found that not only did the inner ring show the greater spacing variation from protein to protein, but also it generally showed a spacing increase on wetting. Both these properties would be expected if, as had been inferred from keratin, the reflexion represented the lateral separation of the main chains in the direction of the side-chains, and the evidence was in fact accepted as establishing the inference.

In the same investigation, among the preparations examined were egg and serum albumins that had been denatured (and coagulated) by heat. The obvious change brought about by this treatment was seen to be a marked sharpening of the backbone reflexion, and, less obvious, the appearance of at least one other outer ring of spacing about 3.6 Å. (see Figs. 1a and 1b). In short, it became clear—that the denaturation and aggregation of a corpuscular protein leads ultimately to a diffraction pattern like that given by disoriented β -keratin. When keratin is stretched from the α - to the β -form, the side-chain reflexion remains and a strong backbone reflexion arises by the process of flattening the polypeptide grids—pulling out the folds, that is, that lie in planes transverse to the side-chains. This is a mechanical operation, but it appeared now that a similar sort of change could be brought about in the structure of the corpuscular proteins by thermal agitation, for example. (Later, it was shown⁷ that the muscle protein, myosin, belongs to the same molecular family as keratin, and myosin can give either an oriented β -photograph by stretching or a disoriented β -photograph by heating.) In some way, therefore, the arrangement inside the corpuscular proteins was a generalization of the α -keratin idea; the situation was like α -keratin only more so. The polypeptide chains were there, but presumably they were folded and grouped in specific configurations from which in most cases they could be liberated fairly easily to produce a variety of non-specific configurations. Subsequent aggregation (at least as regards the more organized regions that are responsible for the regular diffraction pattern) in-

volved a building of 'crystallites'—sometimes more perfect, sometimes less perfect, but at any rate of the type of the aggregates of polypeptide grids that constitute the crystallites of β -keratin. (Denaturation of a corpuscular protein as here described is the thoroughgoing irreversible phenomenon as it is usually understood in Great Britain. Reversible loss of solubility and specificity is sometimes described as 'reversible denaturation', but such changes are conceivable without disorganization of the molecule as a whole. Sometimes, too, no clear distinction is recognized between denaturation and the aggregation of proteins that are already in an extended configuration⁸. Myosin 'denatured' by simple drying is still in the folded α -form, but there is disorganization of the folds if it is heated.)

It followed at once from this line of argument that if, after unfolding the polypeptide chains, they could be drawn parallel, or approximately parallel, then artificial fibres would result; and the test would be the production of an oriented β -photograph. Decisive orientation effects were first obtained with denatured preparations of the seed globulins, edestin (from hemp seed) and excelsin (from Brazil nuts), and also with 'poached' egg white⁹; while the first actual fibres were spun from strong urea solutions⁹. When edestin, for example, is dissolved in strong aqueous urea, the solution in time becomes very viscous, and elastic fibres may be produced either by drawing out the viscous mass or by squirting it through a capillary tube into water or dilute salt solution. (This sort of observation is not new, but it seems that X-rays first clearly exposed the reason for the rise in viscosity—the unfolding of round molecules to give polypeptide chains in extended configurations.) In general, though, such fibres have to be stretched farther in order to reveal definite orientation effects in the X-ray photographs. As a matter of interest, some of the early diffraction patterns are reproduced in Fig. 2. They illustrate the first demonstration by X-rays of the transformation of an originally crystalline protein into an elastic fibrous structure.

Fig. 2. (a) DISORIENTED β -KERATIN; (b) ORIENTED β -KERATIN; (c) DISORIENTED DENATURED EDESTIN; (d) ORIENTED (STRETCHED) DENATURED EDESTIN.

Fig. 3. ARDIL FIBRES.

Experiments on continuous fibre production from urea solutions were then conducted in Prof. A. C. Chibnall's laboratory at the Imperial College of Science and Technology, London; but later, though considerable further advances were made, it was felt better to return to the more fundamental side of protein research. Thereafter, as indicated above, the production of 'Ardil' (see Fig. 3) and its development to commercial satisfaction was the work of chemists of Imperial Chemical Industries, Ltd.¹⁰ 'Ardil' is produced from the peanut globulin, arachin, and the original urea process has now been replaced by extraction and 'maturing' with dilute alkali; also, striking new after-treatments have been evolved for improving the tensile properties of the fibres and their resistance to dyeing and finishing processes. Actually, the present stage of development was reached by the beginning of the War, but since then further work has been held up.

'Ardil' is a cream-coloured, crimped, elastic fibre that is soft and warm: it is a kind of artificial wool without surface scales. It greatly enhances the felting of wool, however, and dyes like wool, but it is not attacked by moths. Its elasticity arises from the circumstance that the unfolding of the original corpuscular molecules is imperfect, vestigial folds remaining that are an irregular counterpart of the regular α -folds to which the elasticity of keratin is due. As now produced, 'Ardil' shows no orientation in its diffraction pattern, but an oriented β -pattern begins to appear on stretching. Fabrics have been made purely of 'Ardil', but its best use is likely to be in combination with wool and other fibres. A by-product of its manufacture is, of course, arachis oil, of which peanuts contain 48-50 per cent; furthermore, after the oil and protein have been extracted, the residue can be used for cattle food.

During the last few years a number of important papers have been published in America on the preparation of artificial protein fibres with the aid of detergents¹¹. Products such as 'Nacconol NRSF' (which is essentially dodecyl benzene sodium sulphonate) are found to act as excellent unfolding agents for the corpuscular proteins, and with the technique described it is possible to make fibres much stronger than anything reported previously. Using egg albumin, for example, the complex formed by mixing equal portions of 3 per cent solutions of re-crystallized egg albumin and detergent is first precipitated with saturated magnesium sulphate, the resulting 'dough' is drawn out into fibres, which are washed with water and extracted with 60:40 acetone-water solution, and then finally the fibres are stretched by about 400 per cent in live steam. Before the stretching in steam, the orientation in the X-ray diffraction

pattern is of the 'crossed' type first observed with stretched films of poached egg white⁸, that was interpreted as corresponding to chain-bundles broader than they are long; but after the stretching it is as in β -keratin with the chain-bundles lying along the direction of stretching. (The effect illustrated in Palmer and Galvin's paper¹² is slight and was at first thought not to be there; but it is now agreed that before stretching in steam there is no real discrepancy with the 'poached egg effect'. Private communication.) The oriented β -pattern given by these stretched egg albumin fibres is very good indeed: it is shown in Fig. 4, which is a reproduction of a photograph kindly sent me by Dr. Palmer. Egg albumin is one of the most typical and most studied of all the crystalline corpuscular proteins, and here in the end it is made to yield one of the best β -fibre photographs! The wheel has now come full circle.

Fig. 4. FIBRE PATTERN (β -KERATIN TYPE) GIVEN BY EGG ALBUMIN FIBRES PREPARED BY LUNDGREN AND PHOTOGRAPHED BY PALMER AND GALVIN.

Lundgren and O'Connell report that artificial fibres from egg albumin (and from chicken-feather keratin, which also responds to the technique just described) have been prepared with breaking strengths of more than 70×10^3 lb. per sq. in.: to appreciate what this means, it may be noted that in the same table they quote 72-100 for nylon, 46-74 for natural silk, and 17-25 for wool. Incidentally, lest it should seem somewhat indecent these days to talk about using egg white for making fibres, it should be added that the same authors point out that there are available annually in the United States more than 26,000,000 lb. of inedible technical egg white (much of which goes to waste) and more than 170,000,000 lb. of chicken feathers.

X-RAY CRYSTALLOGRAPHIC MEASUREMENTS ON A SINGLE CRYSTAL OF A TOBACCO NECROSIS VIRUS DERIVATIVE

By DOROTHY CROWFOOT

AND

G. M. J. SCHMIDT

Laboratory of Chemical Crystallography, Oxford

IN August 1944, N. W. Pirie, of Rothamsted, sent us a few large crystals of a tobacco necrosis virus derivative (Rothamsted strain)¹ on which we have been able to make some X-ray measurements. Before we could complete the investigation the preparation unfortunately deteriorated, but the crystals are in themselves so remarkable that it seems worth while to give a preliminary account of their characteristics. They are described as of a crystalline derivative rather than as crystals of the virus itself, since by the time the preparation had crystallized it had lost its infectivity. It shows, however, the same serological and ultracentrifugal behaviour as the active material and so probably does not differ greatly from this². The molecular weight indicated by the sedimentation constant is at least 1,850,000, and this order of magnitude is confirmed by our present measurements.

The crystals were of quite unusual size, 1–5 mm. across, and appeared to be of two forms, thick triclinic prisms and thin hexagonal or pseudo-hexagonal plates. They had been grown for more than a year from aqueous solution, and when received were adhering to the walls of the tube covered with a film of moisture. The thickest crystal of all, which was of the first kind and measured approximately 2 mm. × 1 mm. × 0.5 mm., was washed into a drop of 1/10 saturated ammonium sulphate solution and drawn into a thin-walled Lindemann glass capillary which was then sealed off. In this tube it could be examined still covered with a film of liquid.

In form the crystal was a thick prism tending to be elongated along [111] and bounded by well-defined faces, probably {011}, {110} and {101}. In polarized

light it showed low birefringence with oblique extinction when viewed parallel to (100), and approximately straight extinction along [111] when viewed perpendicular to (100), which suggested monoclinic or pseudo-monoclinic symmetry. These measurements could not be made very accurately owing to the position of the crystal in the tube. But in essentials they are confirmed by the X-ray data, which show that the crystal is triclinic, with $a = 179 \text{ \AA}$., $b = 219 \text{ \AA}$., $c = 243 \text{ \AA}$., $\alpha = 87\frac{1}{2}^\circ$, $\beta = 97\frac{1}{2}^\circ$, $\gamma = 97\frac{1}{2}^\circ$ (reduced cell), space group $P1$; and that there is a marked approach to monoclinic symmetry, which is better illustrated by adopting the larger unit cell $a' = 179 \text{ \AA}$., $b' = 303 \text{ \AA}$., $c' = 346 \text{ \AA}$., $\alpha' = 96^\circ$, $\beta' = 101^\circ$, $\gamma' = 90^\circ$, space group $A1$. In the account which follows, the indices given refer to the pseudo-monoclinic cell.

In order to measure these very large cell dimensions, using copper $K\alpha$ radiation, five $2\frac{1}{2}^\circ$ oscillation

Fig. 2. TOBACCO NECROSIS VIRUS DERIVATIVE.

- (a) Crystal 'still'. X-ray beam nearly perpendicular to (h^*00). Reflexions from (h^*00). 12 hours exposure.
(b) Crystal 'still'. X-ray beam 60° from (h^*00). Reflexions from (h^*00), ($4h^*k^*0$), ($3h^*k^*0$). 10 hours exposure.

photographs were taken of the crystal rotated about the normal to (001), with a plate-to-crystal distance of 10.1 cm. (Fig. 1). The X-ray beam was defined by a lead glass capillary of bore 0.025 cm. kindly lent to us by Dr. W. T. Astbury. With this slit system there is some blurring of neighbouring hkl reflexions for which the index k varies only by 1, since the interval, $b = 303 \text{ \AA}$., is outside the theoretical limit of resolution; but since there are sharp reflexions with indices $0kl$ differing by various multiples of k , the lattice is defined unambiguously. Apart from this difficulty, the patterns of the X-ray reflexions on the oscillation photographs are exactly comparable with those found on simpler crystals, the only difference being one scale.

This difference of scale makes it possible, however, for us to estimate the unit cell dimensions in quite a different way on a new variety of X-ray photograph. The unit cell dimensions are so large that, even when the crystal is kept stationary, innumerable crystal planes are geometrically in a position to reflect monochromatic X-rays. Photographs obtained with the crystal 'still' accordingly show numbers of X-ray reflexions, and these, though individually unresolved, are characteristically arranged on the plate in series of concentric circles, or ellipses (Fig. 2). Their arrangement is most easily understood by referring the process of reflexion in the usual way to the interaction of the crystal reciprocal lattice with the sphere of reflexion^{3,4}. In reciprocal space the lattice points are crowded together so that many will be in contact with the sphere of reflexion in any position of the

Fig. 1. TOBACCO NECROSIS VIRUS DERIVATIVE.

$2\frac{1}{2}^\circ$ oscillation photograph, crystal rotating about normal to (001), X-ray beam parallel to (100). 90 hours exposure.

crystal relative to the X-ray beam. The points are, however, grouped into reciprocal lattice planes, and these intersect the sphere of reflexion in circles, where the interval between two concentric circles depends on the spacing of the series of parallel reciprocal lattice planes and hence inversely on the crystal cell dimensions. The diagrams in Fig. 3 illustrate the process.

Since only reciprocal lattice planes with large spacings and in a position not far from normal to the

Fig. 3. INTERACTION OF RECIPROCAL LATTICE PLANES WITH THE SPHERE OF REFLEXION (a) IN PERSPECTIVE, (b) IN PROJECTION. AA', BB', CC', reciprocal lattice planes; O, centre of sphere of reflexion; PP', photographic plate.

beam direction can give well-defined circles or ellipses when projected on to the photographic plate, three or four 'still' photographs at intervals of 30° or so serve to define the lattice normal to any particular rotation axis. In the present case we first deduced two of the three reciprocal cell dimensions from a series of 'still' photographs which showed reflexions from the reciprocal lattice planes (h^*00) , $(0k^*0)$, (h^*k^*0) , $(h^*\bar{k}^*0)$, $(2h^*k^*0)$, $(3h^*k^*0)$, $(4h^*k^*0)$, (h^*2k^*0) and $(3h^*2k^*0)$, and afterwards took the oscillation photographs when we knew the degree of resolution we should need. With our apparatus a good 'still' photograph at a plate-to-crystal distance of 4 cm. could be obtained in twelve hours, while the best oscillation photograph took ninety hours. As these exposure times with our X-ray tubes were so long, we transferred the crystal, at the kind invitation of Sir Henry Dale, to the Davy Faraday Laboratory, at the Royal Institution, London, for photography with a more powerful tube. One trial photograph was taken in four hours, but at this stage an accident to the crystal prevented further work. In all, the crystal was exposed for approximately five hundred hours to X-radiation without apparent deterioration.

While the 'still' photographs provide good evidence on the cell dimensions, we have to turn to our very limited series of oscillation photographs for further details of the crystal structure. One striking feature of the X-ray photograph reproduced (Fig. 1) is the absence of a number of reflexions, $h0l$, where h is odd, which suggests that there is a pseudo-glide plane of symmetry present and that the arrangement of the molecules in the crystal approximates to that required by the space group Aa . In this event there must be four units in the face-centred unit cell or two in the primitive cell measured above. In the absence of measurements of crystal density and of water content, we can only give a rough estimate for this unit molecular weight based on measurements of

these quantities on other virus crystals. If we take the figures for the crystalline bushy stunt virus⁵, water content 55 per cent, density 1.286, the molecular weight of the tobacco necrosis virus derivative can be calculated as 1,600,000. But since the nucleic acid content of tobacco necrosis virus is higher than that of bushy stunt virus, it is probable that the density is greater, and this figure may therefore be regarded as a lower limit for its molecular weight. As such it compares well with the ultracentrifuge figure given above, 1,850,000, which is also a lower limit calculated⁶ for a spherical molecule with the observed sedimentation constant, 50×10^{-13} .¹ Actually the crystal structure suggests that the molecules do not differ in shape very markedly from spheres. On this view the estimated molecular dimensions vary from about 80 Å. as a minimum radius to a possible maximum of 100 Å. radius in one direction.

The presence of even a pseudo-glide plane of symmetry in the crystal structure of a molecule certainly containing asymmetric centres may appear at first sight odd. But this effect again must be due to the enormous size of the molecule. It has only been observed so far for reflexions with spacings greater than 25 Å., and the intensities of these can be sensitive to little more than the general shape and position of the molecules in the unit cell. With fresh material we hope to be able to extend our survey of the X-ray reflexions and to obtain a better idea of the actual dimensions of the virus molecule. That the required X-ray data can be got is proved by the 'still' photographs, which show X-ray reflexions from planes with spacings as small as 2.8 Å.

OBITUARIES

Sir Thomas Lewis, F.R.S.

SIR THOMAS LEWIS died on March 17, at the age of sixty-three, when still in full mental vigour. He leaves behind him a long train of brilliant achievements; and the path through which he moved for the illumination of medical science by clinical research will not remain void, for in the last twenty years of his life he had devoted his chief thoughts to the firm establishment of a group of men who understood his aims and would maintain their impulse.

Lewis himself was as distinguished for his researches in pure physiology as for his clinical authority in the diagnosis and care of heart disease. Yet neither field taken alone could satisfy him. He desired intensely the progress of medical skill, for he had seen the abundance of clinical problems waiting for study by precise scientific thought. Knowledge would not come quickly enough and many clinical questions would remain untouched if they were left to pathologists or physiologists for an answer. So he strove for the recognition of clinical science as a separate member of the group of biological sciences, a member that would make use of any of its sister sciences and yet be sovereign within its own clinical jurisdiction.

As the Physiological Society has been founded to bring physiologists together in helpful debate and fellowship, so Lewis in 1930 founded the Medical Research Society and transferred to it his journal *Clinical Science* with the aim of giving to that band of scientific workers their own tourney ground. The success of such a movement to bring scientific ways of thought into the heart of clinical experience was the dearest of Lewis's hopes, and despite his untimely death it will not now fail.

Lewis came of pure Welsh lineage, perhaps the most distinguished man of science as yet given to the world by the Principality. His father had an important place there in mining, having been president of the Coal Owners' Association; but Lewis when quite a young boy had preferred medicine for the quaint reason that the family doctor had delighted him by being a skilful conjurer. It was the side delights, apparently inhering in medicine, rather than the straightforward work of a doctor that entranced him. His abilities were soon proved by scholarships and gold medals in progress through medical training at Cardiff and later in London. But all this time his mind was finding chief satisfaction in the laboratories of physiology, where he had begun research and published papers even before qualification. In London, through acquaintance with Starling, Cushny and Leonard Hill, all busy with problems of the circulation, he met James Mackenzie and discussed with him the nodal rhythm that the latter had proposed in explanation of the particular type of irregularity of the heart-beat which he had studied clinically by venous tracings. Einthoven in Holland had recently devised a delicate galvanometer which could be used for analysis of the heart's action in man. Lewis seized the vital chance, obtained the instrument, and with it quickly proved, in 1909, that the particular irregularity in man was due to auricular fibrillation. This mechanism had been earlier identified in animal experiments by Cushny; but the physiological discovery was waiting its application to analysis of disorders of the human heart. The application was

relatively easy and it was made at the same time by workers in Vienna. But Lewis's genius, now that fortune had granted him this opening to fruitful research, moved far and fast with it. He concentrated all his clinical experience upon analysis of the forms of irregular heart-beat, identifying each by its galvanometric curve and then studying separately the prognosis and treatment of each form. But more profound analysis of the character of each electrical curve of irregularity was needed, and to this end Lewis commenced a series of experiments on the dog's heart, delicate and difficult instrumental studies involving exact analysis of the time relations of the electric change at successive points, inner and outer, along the walls of the double-chambered ventricle. These measurements traced the path of the wave of contraction, and so gave the first analysis, in 1916, of the *PQRS* curve in the normal electrocardiogram. From this followed in 1920 a satisfactory account of the sites of origin in the human heart of the various forms of irregularity seen in disease.

Meantime Lewis had come to a clear decision as to what his life in medicine was to be. He desired research based continually on clinical experience. In 1910 the newly created Beit Fellowship had given him freedom for three years to follow this aim. Soon after that came the War and Lewis was attached to a special military hospital for study of the soldier's heart. In 1916 the Medical Research Council offered him a permanent position on its external staff, and Lewis gladly accepted this escape from the road that would have rapidly led to a great consulting practice in heart disease but away from intense and progressive research. At the end of the War he returned to the staff of University College Hospital and the enjoyment of a laboratory adequately staffed by the Medical Research Council. But he had shown during the war period that important discoveries could be made by use of the simplest apparatus, such as a sphygmomanometer, provided it were guided by subtle thinking; and his demonstration in 1916 of the contractility of the capillaries by adrenalin led him to the exploration later of entirely new fields of his own. The results were summarized in 1927 in his book on the "Bloodvessels of the Human Skin", in which he analysed their nervous control and particularly their inflammatory reaction to a chemical substance, akin to histamine, found by him to be normally released upon injury to skin cells. This idea of an autochthonous chemical irritant of nerves, now running parallel with the discoveries of physiology in respect of cholinergic nerves, was later extended by Lewis to include some forms of pain, for example that of angina pectoris; and from that he was moving to a hopeful investigation of deep visceral pain, a matter of intense importance to clinicians, when in 1939 war again came and ended the work.

Lewis had been elected fellow of the Royal Society in 1918, at the early age of thirty-six, and in 1941 he received its Copley Medal, the highest recognition that British science can give for fundamental discovery. Not since Lord Lister, in 1902, had this award been made to an active clinician. His world-wide reputation naturally brought him the honorary membership of many learned societies and the degrees of many universities at home and abroad. In practical medicine the teaching of two books upon heart diseases, which he wrote deliberately for medical practitioners—and they were translated into several foreign languages—had a transforming influence so

complete that it is now almost forgotten that the change was largely due to his researches. Otherwise he refused to spare time for routine discussions at medical societies, for he had no wish to stay fixed on a summit as an acknowledged heart specialist. Independence had been given to him by that intensely important move of the Medical Research Council when it led the way in creating whole-time posts for clinical research, and so he could go wherever his genius beckoned. With his amazingly clear and penetrating intellect he was the mainstay of scientific progress in all departments of his medical school at University College Hospital. Young or old, but especially the former, found him eager and ready to help them. He had the devotion of a zealot to his cause, but a devotion that had no self-seeking or personal conceit to mar it. And work was not all. There was time for pleasures of the countryside, a garden, trout fishing, and especially watching the wild birds that he knew so intimately and photographed with such artistry. Friendships, not readily accepted but staunchly held, also played their part, but chief of all was his happiness in married life.

T. R. ELLIOTT

Mr. W. E. Nicholson

WILLIAM EDWARD NICHOLSON, who died at Mullion, Cornwall, on February 13, was, after his life-long friend, H. N. Dixon, the best known authority in Great Britain on the taxonomy of the bryophytes. He was interested particularly in the European mosses and in European and exotic hepatics.

By profession a solicitor, Nicholson was born in 1866 at Lewes, Sussex, where almost the whole of his life was spent. He was educated at Marlborough until ill-health compelled him to leave at an early age. From boyhood he was deeply interested in natural history, and until middle life as much in entomology as in botany. Towards the end of the last century, Nicholson began the study of the mosses and liverworts, receiving help and encourage-

ment from William Mitten, the veteran Sussex bryologist and the greatest authority on the exotic mosses of his day. Later he came into contact with H. N. Dixon, and the two soon gained an international reputation for a number of remarkable additions to the European flora made on journeys ranging from southern Portugal to Tornean Lapland.

Though without a scientific training, Nicholson had a keenly critical mind and abnormally acute powers of observation, which were strikingly shown by the extraordinarily large number of species he was able to discover in his native Sussex, including many of the minute and elusive species of *Cephaezella*.

Nicholson wrote a number of short papers on British and foreign bryophytes, among which his papers on the mosses and liverworts of Sussex were particularly noteworthy. In his later years most of his time was devoted to exotic hepatics, and his most important work in this field was his account of the Chinese collections of the Freiherr von Handel-Mazzetti published in *Symbolae Sinicae* in 1930.

Besides botany, Nicholson's chief interest was in archaeology, and he was for fourteen years secretary of the Sussex Archaeological Society.

P. W. RICHARDS.

WE regret to announce the following deaths

Dr Denis Coffey, formerly president of University College, Dublin, and vice-chancellor of the National University of Ireland, on April 3, aged seventy-nine.

Sir Ambrose Fleming, F.R.S., on April 18, aged eighty-five.

Mr A. R. Hinks, F.R.S., C.B.E., secretary of the Royal Geographical Society since 1915, on April 14, aged seventy-one.

Dr Bohuslav Vrbenský, a Czechoslovak medical man, who held office as Minister of Health and Minister of Public Works in several Governments, and in particular was instrumental in securing improved working conditions for Czechoslovak miners, on November 25, 1944, aged sixty-two.

NEWS and VIEWS

Pure Mathematics at Cambridge :

Prof L. J. Mordell, F.R.S.

THE election of Prof L. J. Mordell as successor to Prof G. H. Hardy in the Sadleirian chair of pure mathematics at Cambridge will not have come as a surprise to those who are aware of his international reputation as a leading British mathematician. His main interest has always been in the theory of numbers, and to this subject he has made perhaps as great an original contribution as any mathematician in Britain, past or present. Among outstanding achievements one may mention (1) the proof that all rational solutions of a cubic equation $f(x,y) = 0$ can be derived by a well-known rational process from a finite number of them (Mordell's finite basis theorem), (2) his work on the representation of a number as a sum of squares, which has its root in Mordell's mastery of the theory of modular functions, (3) his work, mostly in recent years, on the geometry of numbers, where he has opened up new avenues of investigation. Characteristic of Mordell's work is

the significance of the problems he has formulated and attacked. The advances he has made, apart from their intrinsic importance, have often been the starting point for work by other distinguished mathematicians.

Mordell went from Philadelphia to St John's College, Cambridge, in 1907 with a senior scholarship in mathematics awarded on the scholarship examination of December 1906. He was third wrangler in the 1909 Tripos. After being lecturer at Birkbeck College, London, he went to Manchester, where he has been Fielden professor of pure mathematics since 1923. In 1941 he was awarded the De Morgan Medal of the London Mathematical Society (of which he is now president). From about 1933 onwards, Mordell gathered round himself at Manchester a group of mathematicians from all over the world, whose interests were mainly in number-theory. The success of the 'Manchester school' in original work owed everything to the fertility of Mordell's suggestions, to the keen interest and zest with which he followed their discoveries (even the least significant),

and to the constant inspiration of his own work. It cannot be an easy task to succeed Prof Hardy, but we can feel confident that the high tradition associated with the Sadleirian chair will be fully maintained.

Prof. E. R. Gilliland

PROF EDWIN RICHARD GILLILAND, professor of chemical engineering at the Massachusetts Institute of Technology, has been awarded the Leo Hendrick Baekeland Award of the North Jersey Section of the American Chemical Society, "for outstanding achievement in the fields of heat transmission, diffusion, distillation, and high-pressure synthetic chemistry". The award, consisting of 1,000 dollars in cash and a gold medal, is to be given biennially to an American chemist less than forty years of age in recognition of accomplishments in pure or industrial chemistry, and was founded to commemorate the technical and industrial work of the late Dr Baekeland. Prof Gilliland, who is thirty-six, is at present working in the Office of Scientific Research and Development, Washington, D.C. He is known as an advocate of the maintenance of a post-war synthetic rubber industry in the United States as essential to the national interest. Prof Gilliland joined the teaching staff at the Massachusetts Institute of Technology as instructor in 1934, and in 1944 was made a full professor.

Prestwich Prize of the Geological Society of France

PROF W. B. R. KING, Woodwardian professor of geology in the University of Cambridge, has been awarded the Prestwich Prize of the Geological Society of France. This prize is the only one which the Society can give to a non-member, and has been given to Prof. King in recognition of his distinguished researches and also for his services to France in "la géologie militaire" during the War of 1914-18 and 1939-45 as geological adviser to the British Army.

Medal of the Liverpool Geological Society

THE Liverpool Geological Society has awarded its medal to Dr Douglas A. Allan, director of the Royal Scottish Museum, Edinburgh, in recognition of his original geological work, mainly on problems connected with the structure and petrology of the Highland Border of Scotland and Angus. The award is also an acknowledgment of the great services rendered to the Society by Dr Allan during the fifteen years he spent in Liverpool as director of the City museums. He has edited its *Proceedings* for fourteen years, and by his lectures and writings has done much to develop and extend an interest in geological science which has been of great benefit to the Society.

Antonín Bělohoubek (1845-1910)

THE centenary of the birth of the elder of the brothers Bělohoubek falls on April 28. Overcoming initial disabilities, both these Czechs became distinguished chemists and influenced the progress of science in Central Europe. Born at Jeřice in Bohemia, Antonín Bělohoubek was the pupil of Balling and began his scientific career as a demonstrator at the Prague Technical College in 1865. He was appointed *docent* in 1871 and professor of applied chemistry and the technology of fermentation in 1880. In this field he was a pioneer in utilizing the microscope to study

biochemical problems. His published researches, mostly conducted during the 'seventies and 'eighties of last century, relate mainly to contemporary analytical procedure. From chemical and bacteriological investigations of thermal and river waters he was led to make geological surveys, and to take an interest in water purification and the disposal of industrial fluids.

Antonín Bělohoubek came before the general public in Central Europe in 1887 during the controversy concerning the genuineness of certain old Czech manuscripts found at Kraluv Dvůr in 1818, for he was the expert called in to make the microscopic and chemical examination. He was also the first to show that chloroform could not be obtained from methyl alcohol by the use of bleaching powder. Later, he became director of the chemical section of the Austro-Hungarian Patent Office in Vienna, but eventually returned to Prague, where he died in 1910. His brother, Augustus Bělohoubek (1847-1908), became lecturer in pharmacy at the Prague Technical College and is best known for his comprehensive survey of the solubility of organic compounds. He also wrote a treatise on drugs that had a considerable vogue towards the end of last century.

Exchange of Diagrams and Data between Radiotherapy Centres

MEDICAL physics is rapidly expanding into an important and well-defined branch of applied physics. At the present stage of development much information is becoming available for everyday use in hospitals, but the information is scattered through a number of journals and sometimes difficult of access. Of particular importance is the distribution of radiation throughout the soft tissues of a patient during irradiation with high-voltage X-rays or gamma rays. This distribution of radiation is a complex function of the physical conditions, and recently Prof W. V. Mayneord published a set of X-ray isodose curves giving data of direct practical application. At a meeting of the Hospital Physicists' Association it was suggested that this idea might be applied to telerradium isodose curves, and to other data. It was thought that often graphs and diagrams which appear in the literature were too small to be useful, and that many workers would like to have full-size copies of the originals. In addition, various institutions accumulate diagrams, nomograms, and data for their own use, which would be very useful to others if an interchange of copies could be arranged.

The Hospital Physicists' Association therefore appointed a sub-committee with Dr John Read, of the London Hospital, Whitechapel Road, London, E.1, as secretary. This sub-committee has collected lists of diagrams, data, etc., which institutions are willing to lend for reproduction, and prepared a catalogue of copies which can be supplied. The catalogue includes books not easily obtainable, a short loan of which can be arranged. Some idea of the contents of the catalogue may be gathered from the fact that it covers isodose curves of a large variety of size of field and other conditions, distributions of energy in X-ray spectra, isodose curves around radium tubes and needles of various sizes, and the distribution and amounts of radium to be used to obtain uniform fields in various conditions, photo-electric absorption coefficients in various elements, energy absorption in water and other biological media, and tables of electronic functions.

Chemical Society : Annual General Meeting

THE annual general meeting of the Chemical Society was held in London on April 19, the president, Prof V N Haworth, in the chair. During the business portion of the meeting, Prof Haworth referred to a letter he had received from N Derzhavin, conveying greetings from men of science in Latvia and directing attention to the crimes committed by the German invaders on the Latvian people, and his proposed reply was read and endorsed. Prof Haworth also agreed to convey the deep sympathy of the Council to the American Chemical Society on the loss of their great national leader, and also greetings to the Belgian, French and Russian Chemical Societies, expressing joy at the liberation of their countries from the foreign invader. In presenting the Report of Council for 1944, reference was made to the retirement of the general secretary and to the following resolution passed by the Council: "The Council has received with profound regret the news of the coming retirement of Mr S E Carr from the office of General Secretary. It desires to place on record its deep feeling of gratitude for the great services he has rendered to the Society over a period of forty-two years." It was declared that Prof H V A Briscoe had been elected honorary secretary, and the following as new members of Council as *Vice-Presidents*, Prof. A J Allmand, Prof J W Cook and Prof M Heilbron, as *Elected Ordinary Members of Council*, Prof Wilson Baker, Mr R P Bell, Prof L T S Britton, Dr D H Hey, Dr B Jones, Dr J. W Le Fèvre, Prof J. M Robertson, Dr F S Spring, Dr M Stacey and Prof A R Todd.

Philosophical Magazine

THE *Philosophical Magazine* is now within two years of celebrating the hundred and fiftieth anniversary of its first publication. The outlook of physical science has changed in the intervening years almost beyond recognition, and it has seemed desirable to the proprietors of the journal to alter the title, while retaining the familiar name of the *Philosophical Magazine*, in such a way as to indicate more clearly the scope of the journal. The old read "The London, Edinburgh and Dublin Philosophical Magazine and Journal of Science, being a continuation of Tulloch's 'Philosophical Magazine', Nicholson's 'Journal' and Thomson's 'Annals of Philosophy'." The new title, which appears for the first time in the current number, "The Philosophical Magazine, a Journal of Theoretical, Experimental and Applied Physics." The journal has had a long and distinguished career and has numbered among its editors some of the most eminent physicists of the nineteenth and twentieth centuries. Its pages have appeared many papers of fundamental importance, during the present century, for example, classic papers by J J Thomson, Rutherford, Bohr and Rutherford have been published in the journal which, despite a marked increase in the number and publications of the learned societies, still holds an honoured place among its contemporaries.

New Theory of the Origin of the Planets

A BRIEF reference is made in the *Observatory* of December to a new theory of the origin of the planets, which, according to the *Moscow News*, was communicated to the Academy of Sciences of the U S S R on June 1, by O J Schmidt, of Arctic fame—a celebrated mathematician and geophysicist. The theory is based

on the rotation of the galaxy, as a result of which two stars sometimes approach so closely that the capture of one by the other occurs, a stable system—a binary—being formed. A star—our sun, for example—passing through one of the meteorite clouds in the Milky Way captures part of the meteorites, and this capture leads to the formation of planets revolving round the sun. It is stated that Schmidt's theory leads to mathematical formulæ which agree with astronomical observation, but it is necessary to suspend judgment until the original paper is available.

Isovol Map of the South Wales Coalfield

AN important contribution to our knowledge of the coals of South Wales has been issued by the Fuel Research Organisation of the Department of Scientific and Industrial Research in the form of an isovol map (1s 3d) and an explanatory booklet (6d.) which describes how the map was compiled, its implications and uses (*Fuel Research Survey Paper No 56*). Both are published by H M Stationery Office, 1944. The 'isovols' plotted on the map are lines of equal volatile content and show graphically the results of the determinations of volatile matter in samples of all the seams so far examined. Further editions will be issued as the survey proceeds. Since volatile matter constitutes, especially in South Wales, a valuable index of the physical and chemical nature of the coal, the map summarizes much of the work of the coal survey in this area up to date, and shows, simply and accurately, where each of the widely differing types of coal occurs. The booklet describes methods of analysis and contains a useful discussion of the relationships between volatile percentages, carbon percentages, calorific value and caking properties—all important factors in assessing the value of the coals.

British Simuliidæ

THE Simuliidæ or 'black flies' are represented in Britain by nineteen species. Their larvæ and pupæ are always aquatic, and the adult females are active blood-suckers. In the British Isles the attacks of the adult insects on man are seldom more than a nuisance, but to horses and cattle they cause much irritation and the animals are often compelled to seek shelter at times when they should be feeding or resting. In such circumstances they will not thrive or put on weight as they should do in normal circumstances. A useful guide to these insects entitled "The British Simuliidæ" by Dr John Smart has recently come to hand. It is published by the Freshwater Biological Association, Wray Castle, Ambleside, from which it can be purchased, price 2s 6d. The pamphlet is well printed and admirably illustrated with numerous original figures. By its aid it should be possible to identify not only the adults but also the larvæ and pupæ of these insects.

University Electoral Registers

IN view of the impending general election in Britain, Mr D Veale, registration officer, University of Oxford, writing on behalf of all university registration officers, urges every voter for a university constituency who has changed his address since registering as an elector and who has not notified the electoral registration officer of his university of such change, to do so as soon as possible. Prompt response to this appeal would not only save many last-minute applications

for voting papers but would also help to ensure that those who have a right to receive voting papers receive them in time to record their votes

The Night Sky in May

New moon occurs on May 11d 20h 21m UT, and full moon on May 27d 01h 49m. The following conjunctions with the moon take place: May 8d 16h, Mars 4° N, May 9d 11h, Venus 7° N, May 9d 23h, Mercury 2° N, May 15d 03h, Saturn 0.2° S, May 20d 11h, Jupiter 4° S. Occultations of stars brighter than magnitude 6 are as follows: May 15d 20h 23m, δ Gem. (*D*), May 15d. 20h 56m, δ Gem. (*R*), May 16d. 21h 27m., 49 B. Canc. (*D*). The times refer to the latitude of Greenwich and *D* and *R* refer to disappearance and re-appearance respectively. Mercury rises about half an hour before sunrise throughout the month and will not be an easy object to observe. It reaches its greatest westerly elongation on May 11. Venus is conspicuous in the eastern sky, rising an hour before the sun on May 1 and about an hour and a quarter before the sun on May 31. The planet is stationary on May 4 and May 24. Jupiter can be seen throughout the early morning hours, setting at 3h 11m, 2h 15m and 1h 10m at the beginning, middle and end of the month, respectively. Saturn is becoming more difficult to observe as it sets at midnight on May 1 and at 22h 26m on May 31. The η Aquarid meteor shower is due in the early part of May. The meteors appear in the early morning hours but moonlight will interfere with observations.

Comments on Chromosome Structure

In *Nature* of April 21, p. 471, an article by Dr I. Manton under this title was published. The accompanying illustration, however, was very unsatisfactory, due apparently to defects in the block. Accordingly a new block was prepared and the illustration is repeated below, with the explanatory legend

Announcements

SIR JOHN ORR, professor of agriculture in the University of Aberdeen, has been elected a member of Parliament for the Scottish universities, taking the place of Mr G. A. Morrison, who has resigned.

THE following appointments have been made in the University of London:

Dr Edmund Giffen, since 1940 director of research at the Institution of Automobile Engineers, to the University chair of civil and mechanical engineering, tenable at Queen Mary College, from October 1, 1945.

Prof. Harold Davenport, professor of mathematics at University College, Bangor, to the Astor chair of mathematics at University College, from October 1, 1945.

DR. NORMAN WRIGHT, director of the Hanna Dairy Research Institute, who has been undertaking a survey of the livestock in the Middle East territories during the past five months, has interrupted his tour in order to make a brief visit to Ceylon, where he is to advise the Ceylon Government on the future development of the cattle and dairy industries of the island. Dr Wright will shortly resume his Middle East tour. He is expected back in Great Britain by the end of June.

THE International Commission on Zoological Nomenclature announces the election of Dr James I. Peters, curator of birds, Museum of Comparative Zoology at Harvard College (assistant secretary to the Commission), to be vice-president of the Commission in succession to the late Dr C. W. Stiles, Smithsonian Institution, Washington.

THE following appointments have recently been made in the Colonial Services: J. E. Cobby, to be assistant conservator of forests, Kenya; K. G. N. Willcocks, to be government chemist, Gold Coast; H. Hirst, acting director of agriculture, Malta; to be assistant director of agriculture, Cyprus.

Fig. 1 Unpaired chromosome of *Osmunda* at the first meiotic division after ammonia treatment for spiral structure. Acetocarmine preparation photographed in clove oil by visual light ($\times 2000$).

Fig. 2 Split chromosome at the second meiotic division in *Osmunda* after ammonia treatment for spiral structure, the two chromatids are attached only at the centromere (*c*). Acetocarmine preparation, ultra-violet photograph ($\times 2000$).

Fig. 3 Split chromosome at metaphase of the third spore division in *Osmunda* showing spiral structure without special treatment. Acetocarmine preparation, ultra-violet photograph ($\times 4000$) negative print (the positive of this and others in Manton and Smiles, 1943²).

Fig. 4 Anaphase of the first spore division in *Osmunda* fixed 30 hours after irradiation of the uninucleate spore with X-rays at 2,500 r showing fractures, fusions and abnormally clear spiral structure. Acetocarmine preparation, visual light photograph ($\times 1000$).

Fig. 5 Anaphase of the third spore division in *Todea* after ammonia treatment, showing lateral separation of component strands. Acetocarmine preparation, ultra-violet photograph ($\times 4000$), negative print (the positive of this and other chromosomes in Manton, 1945³).

LETTERS TO THE EDITORS

Kinematical Relativity and the Nebular Red-Shift

PROF J. B. S. HALDANE's far-reaching deductions¹ from Prof. E. A. Milne's "kinematical relativity" excite our admiration, but they must also excite in many a feeling of apprehension lest, in our eagerness to build, we ignore defects in the foundations. Before extrapolating so extensively as Prof. Haldane has done, we should surely ascertain that kinematical relativity can explain what we do know. I have already, in *Nature* and elsewhere, objected to its essentially unscientific character, the purpose of his letter is to point out what seems to me its failure to explain the one fact we have relating to the distant past, namely, the nebular red-shift.

In Prof. Milne's recent letter on "The Ageing of Light"² the "usual Doppler effect" is assumed without comment. That letter, of course, is concerned not with the nebular red-shift, which is shown by light originating in the nebulae, but with the behaviour of hypothetical light originating in our galaxy and supposed to have been reflected to and from the same nebula from the beginning of time until now. Its validity also, however, depends on a satisfactory explanation of an essentially similar phenomenon.

The observation is that nebular spectrum lines are less refrangible than lines emitted here and now from (presumably) similar atoms. We all agree to express the problem thus raised by asking why the frequency of old nebular light is smaller than that of young terrestrial light from similar atoms.

Kinematical relativity answers in terms of arbitrarily chosen time-scales, of which two are particularly relevant: (a) the *kinematic* scale (t -time), in which all 'rigid' bodies are expanding and separating, but the frequency on emission of light from a particular *ind* of atom (Z) is the same at all times, (b) the *dynamical* scale (τ -time), in which the sizes of and distances between rigid bodies remain constant, but the frequency on emission of light from Z is greater the later it is emitted. The red-shift, it is held, is explicable on either scale, but this I cannot see.

Consider first the t -scale. The frequency on emission is the same at all times, but the nebula is receding. Only two causes of red-shift are then conceivable: (1) relative motion of earth and nebula, (2) decrease in frequency of *light* (not atomic processes) during passage through space. General relativity accepts (1), but kinematical relativity cannot do so because it holds that even *relative* motion can be transformed away mathematically, and we cannot attribute an objective fact to a cause destructible by "an arbitrary act on the part of the hinker"³. Neither is (2) available, for in his comments⁴ on Prof. Haldane's paper, Milne says (this seems also to be implied in previous papers, but I have not before seen so unambiguous a statement): "This degradation of the individual photons due to interacting with matter must be distinguished from their constancy of frequency in time (t -scale) as they are propagated through empty space". The only possibility left thus seems to be the arbitrary postulate that inter-nebular space contains matter which affects light in a way unknown elsewhere in nature. This has not to my knowledge been suggested,

and would be a purely *ad hoc*, and therefore worthless, explanation.

The same difficulty in different form is, of course, experienced on the τ -scale. Here the sizes of bodies (and therefore of the atoms which compose them) remain constant, but *atomic frequencies* change with time. Hence atomic frequencies must depend on something unstated which does not affect the linear dimensions, thus apparently ruling out all possibility of correlating radiation with atomic structure. Moreover, if inter-nebular matter is to be admitted, we must suppose its effect on light-frequencies to be exactly neutralized by an *ad hoc* change of light-frequency (on the τ -scale) during propagation through space, for the explanation is complete without change of frequency after emission. But change with propagation, even on the τ -scale, is denied by Milne⁵, so the inter-nebular matter essential on the t -scale becomes fatal on the τ -scale. Kinematical, unlike general, relativity therefore appears unable to account for the red-shift.

This comparative impotence seems to depend ultimately on the restriction of observations to readings of a single clock, which are insufficient data for describing the full variety of physical experience. Consider a missile which, by ordinary measure, is approaching an observer. By the principle which is held to validate the t and τ scales, the observer can properly regard its distance as remaining constant. He has simply to send a beam of light to and from the missile without pause, and regard its successive returns as equally spaced in time. The ultimate impact then does not occur until $\tau = \infty$ on this scale, and so causes no mathematical embarrassment unless the observer survives, but the comfort thus afforded is perhaps questionable. A portion of the observer's experience is made inaccessible in the description given by kinematical relativity, but it is perfectly accessible to him. One cannot help recalling Achilles and the tortoise.

It would, I believe, give satisfaction to many who find a genuine difficulty here if some kinematical relativist would (if possible at no greater length and with no more recourse to mathematics than this letter has required) explain how the theory meets the objection I have tried to express. It is clearly desirable that, before the valuable time of men like Prof. Haldane is further employed in making unverifiable deductions from the theory, we should be assured that the theory can satisfactorily account for what we do experience.

HERBERT DINGLE.

Imperial College of Science and Technology,
London, S.W.7.
Feb 26.

¹ *Nature*, 155, 133 (1945).

² *Nature*, 155, 234 (1945).

³ Milne, E. A., *Astrophys. J.*, 91, 167 (1940).

⁴ *Nature*, 155, 136 (1945).

⁵ *Proc. Roy. Soc. A*, 158, 328 (1937).

PROF DINGLE makes Prof. Haldane's contribution to kinematical relativity the occasion for what he thinks is an attack on its foundations. He is very simply answered: the red-shifts in the spectra of the galaxies are described in kinematical relativity as a Doppler effect due to recession. The consequences of this in relation to the ageing of light and Prof. Haldane's work have been discussed by me in a letter to *Nature* written before I saw Prof. Dingle's letter.

I see no reason to take up Prof. Dingle's challenge to answer his misunderstandings without the use of mathematics. The consequences which he finds so difficult are *mathematical* deductions from a simple model of the expanding universe; I attach no weight whatever to the verbal descriptions I have occasionally attempted—the core of the matter lies in the mathematics. Prof. Dingle takes from time to time certain English sentences of mine and criticizes their content, but I have never felt that he has understood the theory itself, as embodied in the mathematics. It is no use objecting to the results themselves, the critic should find flaws in the trains of mathematical deduction. When Prof. Dingle finds such flaws, I shall be the first to examine the situation, and to attempt to correct the conclusions. Until then, I have nothing to add to my constructive papers.

Prof. Dingle's attempt to pour ridicule on some of the consequences of kinematic relativity reminds me of Bishop Wilberforce's attempt to discredit the theory of evolution. It is the fate of most essentially new theories to be either ridiculed or ignored. Prof. Dingle should remember, for example, that the ideas of non-Euclidean geometry took a long time to become accepted—they are *prima facie* as absurd as he makes out kinematic relativity to be. I have no personal responsibility for the deduction that the Newtonian scale of time is not the scale of time in which the galaxies are receding; it is an inevitable consequence of the circumstance that the equation of motion of a free particle, at large among the receding galaxies, comes out to be non-Newtonian, but becomes Newtonian when the logarithmic change of time-scale is applied. One of the fundamental problems of physics is the question whether the dynamical scale of time is identical with that corresponding to the recession of the galaxies, and to this problem kinematic relativity finds a solution.

I would add that I have repeatedly shown that clock-readings alone are adequate to give measures of epoch and distance—this lies at the basis of modern determinations of *range* (for war-like purposes) by radar, that general relativity, unlike kinematic relativity, is unable to incorporate the essentially *forward* march of time, and that Prof. Dingle uses an antiquated theory of causation which plays no part in kinematic relativity.

E. A. MILNE

Relationship between Nuclear Force and Gravitational Force

ALL we know of nuclear force is that it is of the short-range type. Its analytical form is still obscure, and the meson theory of its origin is, up to the present, inconclusive, to say the least.¹ On the other hand, gravitational force is explained by the theory of general relativity. Temporarily disregarding the theory of general relativity and considering only the important fact that both nuclear force and gravitational force are attractive, let us assume that they are of the same origin. Let us tentatively take the function

$$V = -AeK/r \quad (1)$$

as the mutual potential between any two nuclear particles, for example, between two protons, two neutrons or one proton and one neutron, with A and K as constants. Then, as the distance r between

the particles becomes much larger than K , equation (1) becomes

$$V = -A' - \frac{AK}{r} \quad (2)$$

In this expression, the first term on the right-hand side is a constant and therefore can be neglected. Thus

$$V = -\frac{AK}{r} \quad (3)$$

On the other hand, the gravitational potential between the two nuclear particles of masses M and M' should be given by

$$V = -G \frac{MM'}{r} \quad (4)$$

If the nuclear force and gravitational force are really of the same origin, we must have, from (3) and (4)

$$AK = GMM' = 1.83 \times 10^{-55} \text{ erg. cm} \quad (5)$$

since $G = 6.66 \times 10^{-8}$ and $M = M' = 1.66 \times 10^{-24}$. Recently, Ragan, Kanne and Taschek², from the proton-proton scattering experiment, found that the potential between two protons can be represented by a rectangular well of width $2 \frac{e^2}{mc^2}$ and depth

10.5 Mev. Now, if from our equation (5) we make the Compton wave-length of the electron, that is $K = \hbar/mc = 3.83 \times 10^{-11}$ cm, we get $A = 4.80 \times 10^{-4}$ and if we substitute these values of K and A into (1)

we find the potential $V = 10.5$ Mev. at $r = 1.51 \frac{e^2}{mc^2}$ which is only slightly smaller than the experimental

value of $2 \frac{e^2}{mc^2}$. In fact, if the potential is not

straight rectangular well but a slightly curved one for the same depth of potential a smaller value of V would be expected. If, instead of the equation (1) we take

$$V = -\frac{B}{r} eK/r = -\frac{AK}{r} eK/r \quad (6)$$

as the nuclear potential function, we get the result

$V = 10.5$ Mev at $r = 1.62 \frac{e^2}{mc^2}$, which agrees even

better with the experimental value. Thus we may tentatively state that

$$V = -\frac{B}{r} eK/r \quad \text{for } r > a$$

$$V = -\frac{B}{a} eK/a \quad \text{for } r \leq a \quad (7)$$

for a certain value of a . Since the value of K is not purely arbitrary, but is chosen as the Compton wave-length of the electron, the agreement between the experimental and the calculated value is perhaps not accidental, and may indicate that the electron, as has long been suggested, plays an important part in nuclear interactions. If it is required to avoid the rather artificial way of 'cutting off' the expression (7) at $r = a$, we give an alternative expression

$$V = -Ae \left[\frac{K}{r} - \left(\frac{K'}{r} \right)^n \right]$$

with n lying between 1 and 2, and K' a new constant which may tentatively be put as the Compton wave-

length of the meson, that is, $K' = \frac{\hbar}{m'c} \approx \frac{\hbar}{180 m_e c}$

but this makes the width of the potential well smaller than $1.51 \frac{e^2}{mc^2}$.

It has been shown by M. S. Wang³ that satisfactory values for the binding energy of the deuteron and the scattering cross-section of protons by fast neutrons can be obtained if either of the potential function (1) or (6) is used. It may also be mentioned that since, of all the fundamental particles, the neutrino is the only one the interaction of which with others is, up to the present, entirely obscure, it is possible that the gravitational field is simply a neutrino field which alone, or together with the electron field, causes material entities to attract each other.

Action of Ionizing Radiations on Carotene and Vitamin A

MANY authors¹ have directed attention to the chemical effects of ionizing radiations, with the view of elucidating the sequence of events between the actual absorption of ionizing radiations in tissues and the biological effects which are known to be produced in radiotherapy. Experiments on enzyme and hormone preparations² have shown that the action of ionizing radiations upon aqueous solutions is indirect. It is well known that genetic mutations may be produced by ionizing radiations³, possibly by a direct effect on the hypothetical macro-molecule of the gene.

Some observations are recorded below on provitamin A (β -carotene) ($C_{40}H_{56}$) and vitamin A ($C_{20}H_{30}OH$), indicating that the effect on these fairly large molecules is direct.

It was observed some time ago⁴ that ($\beta + \gamma$) rays from radon in glass capillaries would bleach butter at a range of 8–9 mm from the capillary. It was later established that the colour of butter is due to carotenoids (c. 94 per cent carotene, 6 per cent xanthophylls). Carotene isomers and vitamin A are normal constituents of human blood. In mammals generally, carotene is converted *in vivo* to vitamin A, relatively large quantities of which are stored in the liver. Apart from quite small amounts of carotene in yellow bone-marrow and body fat, mammals store little carotene, and the normal blood-level is only maintained as the result of day-to-day intake of dietary carotene (green vegetables, carrots, butter, etc.). It is obviously of interest to determine the effect of ionizing radiations used in radiotherapy on carotene and vitamin A.

In one series of experiments, it was established that $\beta + \gamma$ rays from radon in glass capillaries and also γ rays from radium in platinum containers destroyed the carotene and vitamin A in butter. Since butter contains c. 15 per cent of water, it was possible that the primary action of the radiation was to activate the water. To test this point, a sample of molten whey butter fat (containing little or no water) was irradiated at 45°C using a current of nitrogen for the dual purpose of stirring and providing a non-oxidizing atmosphere. The destruction of carotene

and vitamin A was complete after exposure to radon in glass capillaries (150 mc. 48 hr). Further, crystalline β -carotene dissolved in pure *n*-hexane was also destroyed, so that effects due to water and oxygen were excluded. Vitamin A, in the form of a rich ester concentrate dissolved in *n*-hexane, was likewise destroyed. In view of the difficulty of estimating the dose in r units from $\beta + \gamma$ rays of radon in glass capillaries, parallel experiments using therapeutic doses of X-rays at 220 kV and 1,000 kV. were carried out with β -carotene in *n*-hexane. In a series of experiments it was found that the 'ionic yield' M/N (M is the number of molecules destroyed, N is the number of ion-pairs produced) was nearly unity, and in one test, at a favourable concentration, exactly unity.

Carotene and vitamin A were present in the butter used in concentrations of 16 I.U./ml. and 20 I.U./ml. respectively (I.U. = 0.6 μ gm. β -carotene), and in blood serum at concentrations of 1–2 I.U./ml. and 0.7–1.3 I.U./ml. respectively.

The action of ionizing radiations on carotene concentrations of 1,000, 100, 10 and 1 I.U./ml. has been tested. The proportion M/M_0 (M_0 is number of molecules present initially) of molecules inactivated is greater in the dilute solutions, as would be expected.

In concentrations of 1 I.U./ml., the absorption of only 64 r of radiation would produce an inactivation of 10 per cent of the molecules. The effect thus approaches in sensitivity Dale's experiments² on the inactivation of enzymes in dilute aqueous solution. These results made it feasible to examine *in vitro* the effect of therapeutic doses of ionizing radiation on the carotene and vitamin A of human blood serum. It was found that 6,000 r of X-rays produced no detectable change, and that exposure to ($\beta + \gamma$) radiation to an extent estimated at 50,000 r was needed to destroy the carotene. The colour-test for vitamin A became quite anomalous (λ_{max} at 595 m μ instead of 617 m μ), which made it difficult to estimate the loss accurately, but probably half the vitamin was destroyed. The nature of the chemical change which causes the colour test maximum to be displaced in this way is imperfectly understood.

The net result of this preliminary work is to establish that there is a direct action of ionizing radiations on provitamin A and vitamin A with an ionic yield of approximately unity in non-aqueous media. The effect is irreversible and is almost certainly accompanied by a loss of physiological activity. In human blood serum the vitamin and provitamin are protected in some way, with the result that by the criterion here adopted, the ionic yield is reduced to 0.01.

Further experiments are in progress and a detailed account will be established elsewhere. One of us (R. A. M.) is indebted to the Medical Research Council for assistance.

Role of Structural Homo- and Heterozygosity in Mosaic Formation

AN investigation into the nature of mosaicism and the regularities of inheritance of mosaic characters in *Drosophila melanogaster* has revealed two essentials. Mosaicism of the ever-sporting displacement type is always connected with a chromosome re-arrangement involving heterochromatin regions of chromosomes. Insertion of extra heterochromatin of X- or Y-chromosome or arms of the latter causes strong suppression of mosaicism.

As my investigations have shown, one of the peculiarities of heterochromatin action in mosaic formation is the maternal effect, that is, extra heterochromatin of the mother greatly decreases the development of mosaic individuals among those of her offspring that have no extra heterochromatin. Further investigations have now shown that the influence of heterochromatin in mosaic formation also exists in the form of a paternal effect. The two types of influence are not specific for any one mosaic strain but are inherent in all mosaic forms of the type of ever-sporting displacements.

The discovery of the paternal and maternal effect of heterochromatin in mosaic formation as well as the uniformity of its action was sufficient to suggest some general mechanism for these phenomena. The existing point of view according to which the action of heterochromatin is to be considered as the result of the breaking down of the quantitative balance between the hetero- and eu-chromatin of the chromosomes of the nucleus is not in agreement with these results.

By studying the influence of different heterochromatin components of chromosomes in a number of mosaic strains, I have collected a large body of data which has made it possible to analyse the regularities of the influence of heterochromatin in mosaic formation. The regularities found are as follows: (1) All heterochromatic components of chromosomes are able to suppress the development of mosaic characters. (2) The influence of extra heterochromatic components in mosaic development is found to exist in the form of a maternal, paternal or immediate (direct) effect. The results of the last-mentioned may be complicated by the additive influence of maternal or paternal effects. (3) Simple quantitative relations of heterochromatin action in mosaicism take place only in the case of the immediate effect when maternal or paternal effects are absent. When these latter are involved, simple quantitative regularity of heterochromatin influence in mosaicism breaks down. (4) Maternal and paternal effects do not follow from simple quantitative relations of hetero- and eu-chromatin, their effect being absent or present even if the quantitative relations of hetero- and eu-chromatin are the same. Only in the case of structural homozygosity of heterochromatin components of the chromosome does the maternal or paternal effect of the influence of heterochromatin in mosaicism take place. In the case of structural heterozygosity both are absent.

Structural homozygosity, in my opinion, means a structural identity in relation to heterochromatin components of chromosomes that secures the complete conjugation of the chromosome during meiosis and possibly during mitosis. It is necessary to emphasize that the term 'structural homozygosity' does not necessarily imply recognition of the pairing of heterochromatin regions, but only recognition of the possibility of their conjugation.

The influence of heterochromatin components of chromosomes in mosaicism in the form of maternal or paternal effects is transmitted from the parents to their offspring by the heterochromatin component themselves, no matter whether heterochromatin is present from a Y-chromosome or from one of its arms, from an X-chromosome or any autosome or from the heterochromatin of a re-arranged chromosome or scute-eight type.

Under the influence of structural homo- and heterozygosity there take place qualitative changes of chromosomes depending upon intracellular processes. I have shown that in homozygous scute-eight females, genetic differences between X-chromosomes can be observed. A chromosome transmitted by the father, owing to its structural heterozygosity, is qualitatively different from one transmitted by the mother.

My genetic studies were verified by cytological investigations (by Prokofieva-Belgovskaya). According to these, one of the X-chromosomes in homozygous scute-eight females has a *heterochromatized* yellow achæte region, while in the opposite X-chromosome this region is *euchromatized*. These differences may go so far as to make the distal ends of the X-chromosome unable to conjugate at all.

Quantitative changes of chromosomes resulting from the influence of structural homo- and heterozygosity are not connected only with mosaic strains. They arise in every stock where the appropriate conditions above mentioned are present. Owing to the instability of its features, mosaicism is only a sensitive indicator, allowing us to detect these qualitative changes of chromosomes.

Since extra heterochromatin leads to euchromatization, it is possible to say that structural homozygosity leads also to euchromatization of chromosomes, while structural heterozygosity leads to heterochromatization of their parts. It is the cause of increased frequency of mosaic individuals under conditions of structural heterozygosity and decreased frequency under conditions of structural homozygosity in genetic structures of type scute-eight. I believe that the phenomenon of heteropycnosis which heterochromosomes undergo in spermatogenesis is the result of structural heterozygosity of X-Y composition. XX composition, being of homozygous structure, does not show heteropycnosis during oogenesis.

Using the phenomenon of structural homo- and heterozygosity in chromosome changes, I have obtained stable changes that have been transmitted during many generations without any decreasing effect.

The data described above enable us not only to understand the nature of mosaicism and the nature of the influence of heterochromatin in mosaicism but also to regard structural homo- and heterozygosity as one of the essential intracellular factors responsible for causing stable changes in chromosomes and then genetic peculiarities. This throws new light on the problem of hybridization, as a factor of variability responsible not only for recombinations of parental characters, but also for new qualitative changes. The importance of the latter is enhanced in the light of recent data on the presence of intrachromosome inert regions, and on the role of chromosome rearrangements among natural populations.

Molecular Rearrangement of Arylimino Diaryl Carbonates

In the course of work on the properties of arylimino diaryl carbonates, we have found that phenylimino diphenyl carbonate (I)^{1,2} rearranges quantitatively to phenyl diphenyl carbamate (II)⁴ on heating at 360° for one hour, or on slow distillation at c 360° no by-products could be detected, and no indication of reversibility of the rearrangement could be found.

This rearrangement of the triad system

recalls the observations of Chapman⁵, who found that N-phenyl benziminophenyl ether, PhC(NPh)OPh, rearranged irreversibly to give N-benzoyl diphenylamine, PhCONPh₂, on heating for one hour at 70–300°

We have been unable to demonstrate a similar rearrangement of the sulphur analogue of (I), phenylimino diphenyl dithiocarbonate PhN·C(SPh)₂, prepared from phenyl carbylamine chloride and sodium thiophenolate. This compound remained unchanged on heating at 330°, and on distillation at c 370° was recovered unaltered, though a little disruptive decomposition may have occurred, indicated by the colour of thiophenol produced. This finds a parallel in the work of Chapman⁶, who found that the sulphur analogue of N-phenyl benziminophenyl ether, namely, PhC(NPh)SPh, remained largely unchanged under conditions which sufficed for the complete rearrangement of the former. At higher temperatures (> 320°), however, decomposition occurred giving products indicative of reversible rearrangement having occurred.

Unsymmetrical analogues of phenylimino diphenyl carbonate, PhN·C(OR₁)(OR₂), where R₁ and R₂ are aryl or aryl groups, have been prepared via the nitrochloride PhN·CCl(OR), and work on their rearrangement, aimed at determining the relative ease of migration of different groups, is in progress and will be reported in full elsewhere.

The rearrangement affords a convenient method for the synthesis of unsymmetrically substituted derivatives of phenyl diphenyl carbamate and hence of phenylamines.

Green Pea Juice as a Medium for the Production of Penicillin

AQUEOUS extracts of ground dried peas form a good medium for the production of penicillin¹. There are, however, certain disadvantages in the use of such material on a large scale, although it forms a very convenient basis for a scheme of fractionation of the active constituents concerned². Last summer we found that a press juice made from entire green peas (seeds and pods) formed an excellent medium for penicillin production. 2,200 gm of entire peas were put through a juice tractor and yielded 1,450 ml (1,520 gm) of juice.

A medium was made up containing NaCl 10 gm, NaNO₃ 3 gm, KH₂PO₄ 0.5 gm, MgSO₄·7H₂O 0.25 gm, lactose 30 gm, pea juice 100 ml and tap water to 1 litre. The pH was 5.8. After mixing well and bringing to the boil, the medium was clarified either by passing through paper pulp or by centrifuging.

The medium was placed either in 40 ml amounts in 250 ml conical flasks or 200 ml amounts in Roux bottles. After autoclaving for 15 min at 15 lb pressure the medium was seeded with a culture of *Penicillium notatum* 1,249 B 21. The flasks were incubated at 24°. Flasks containing the Coghill medium were set up at the same time.

Penicillin production was assayed both by the dilution method and by Brodie's³ method. Typical results obtained were: Pea medium 150 units per ml after 9 days, Coghill medium 150 units per ml after 9 days. With both media values ranging from 125–225 units per ml were found in different flasks.

A striking feature of the pea medium is the rapid covering of the surface of the culture medium.

Yields of 80–100 units per ml were obtained with the diluted pea juice to which only sodium chloride had been added. The residue left after making the pea juice is inactive. The pea juice may be preserved either in a dry form or in the frozen state. The cost of peas to prepare such a medium would be, for peas at 54s per cwt, 9d–10d per gallon of medium.

Assay of the Rates of Secretion of Antibiotic in Different Regions of a Growing Mould Colony

In research on antibiotics, one field is conspicuously blank: that of how a species produces a certain antibiotic. There is no definite answer for any antibiotic to even such elementary questions as: Is the metabolism of the antibiotic linked up with cell multiplication and growth? Is the antibiotic an intra- or extra-cellular metabolite? Is it secreted from the same cells that produce it, or is it secreted from a different part of the mycelium? A technique which may help in solving parts of these problems has now been worked out.

Colonies are grown on disks of permeable 'Cellophane 600' over a very dilute agar medium (for example, Czapek-Dox diluted fifty times). The medium may be kept constant, if the aim of the experiment requires it, by transferring the 'Cellophane' disk with the colony to another Petri dish as often as necessary. When the colony has reached the desired diameter, it is transferred for periods of one hour three or more times on to fresh medium. This removes any appreciable amount of lingering antibiotic. The colony is then transferred on to hard (3 per cent) agar 3 mm deep and left there for a short time (10 min–1 hr) the antibiotic secreted during this time diffuses into the agar. The colony is removed and can be tested again if required. The region of the agar over which the colony was lying is immediately punched all over with a glass tube 3 mm in diameter. The resulting small cylinders of

agar impregnated with antibiotic are then put, face down, on the surface of a testing agar medium (for example, the usual agar-nutrient, *Staphylococcus*). They are arranged in the same disposition as originally, but with proportional increases in the distances between them. The size of the inhibition ring formed after incubation around each agar block gives an estimate of the amount of the antibiotic secreted into the block by the small region of the colony which was in contact with it for the time of testing, that is, an estimate of the rate of secretion.

In the accompanying reproductions, (a) shows an assay on a 10 cm Petri dish of a 5 cm colony of a good strain of *Penicillium notatum*. The rate of secretion of the antibiotic is at its minimum at the centre and the growing edge of the colony, at its maximum about 1 cm behind the growing edge. A good rate is kept up for a considerable distance towards the older parts of the colony. Assays on a 'poor' strain present the same trend (b), but in this case the high secretion is of short duration (growing edge not assayed in this photograph). If synthesis and secretion occurred at the same place, one could deduce that in this species the antibiotic is a metabolic product of already established hyphae, it is not directly connected with cell-multiplication, and its production falls off in old cells, less rapidly so, however, in a good than in a bad strain. By this technique the different rates of secretion of different 'sectors' of a colony can also be estimated.

I am indebted to Mr P. Bruce White for a most helpful suggestion without which this technique could not have been refined.

Hæmoglobins of *Ascaris lumbricoides* var *suis*

ALTHOUGH hæmoglobin has been recorded in a number of species of parasitic nematodes, the occurrence of the pigment in this class of invertebrates, as in most of the others, is sporadic. Little work has been done upon the properties and function of these nematode hæmoglobins.

Keilin observed¹, in *Ascaris lumbricoides* from the pig, two hæmoglobins which differed from each other, and from the hæmoglobin of the host, in the position of the bands in the absorption spectra. The perienteric fluid and body-wall of the parasite each contained a characteristic hæmoglobin. Some further observations have now been made upon these pigments.

When *Ascaris*, kept under strictly anaerobic conditions, was observed spectroscopically, the oxy-

hæmoglobin of the body wall was seen to become deoxygenated. Extracts of this hæmoglobin proved to have a very high affinity for oxygen, it being impossible to secure complete deoxygenation of the oxyhæmoglobin by equilibrating against a vacuum at 20° C. Sodium hyposulphite, which rapidly takes up oxygen in solution, produced a slow deoxygenation. Thus *in vacuo* at pH 7 and 8° C., 250 sec (t_{50}) were required for half dissociation of the oxygen from the hæmoglobin.

Spectrophotometric measurements upon concentrated extracts revealed that the body-wall oxyhæmoglobin has a spectrum of unusual type (Curve 1). The α -band is narrower and less intense than the β -band. Keilin and Wang have recently described an oxyhæmoglobin from the root nodules of a leguminous plant which has a spectrum of similar form. The spectra of other animal oxyhæmoglobins which have been described hitherto have bands of approximately equal height, resembling those of the human oxyhæmoglobin shown in Curve 3. The deoxygenated body-wall pigment has a normal spectrum (Curve 2).

A still greater resistance to deoxygenation is shown by the perienteric fluid oxyhæmoglobin. Under the influence of sodium hyposulphite *in vacuo* at 8° C. and pH 7, $t_{50} = 1,000 \pm 100$ sec. The reaction thus proceeds about four times more slowly than with the body-wall pigment. The effects of various factors upon the velocity of deoxygenation were examined.

(1) An eight-fold variation in the concentration of the reducer was without effect upon the reaction velocity. The reaction is therefore not an oxidation-reduction but a true deoxygenation.

(2) Assuming the temperature effect follows the Arrhenius equation, extrapolation from the curve of temperature against reaction velocity to 37° C. gave a value t_{50} of about 150 sec. Hartridge and Roughton³ deduced that, for sheep hæmoglobin, t_{50} at 37° C. was 0.0025 sec.

ABSORPTION SPECTRA OF (1) OXYHÆMOGLOBIN OF THE BODY WALL OF *Ascaris*, (2) BODY WALL HÆMOGLOBIN, (3) HUMAN OXYHÆMOGLOBIN. ORDINATES: THE ABSORPTION COEFFICIENT

$\beta = \frac{1}{cd} \log_e \frac{I_0}{I}$, WHERE c IS THE CONCENTRATION OF HEMATIN EXPRESSED AS gm. mol./c.c., d IS THE DEPTH OF THE ABSORBING SOLUTION IN cm., I_0/I IS THE RATIO OF THE INTENSITIES OF INCIDENT TO TRANSMITTED LIGHT. ABSCISSAE ARE WAVE-LENGTH OF LIGHT IN μ .

The spectrum of the perienteric fluid oxyhæmoglobin is of the same type as that of the body-wall pigment

The main derivatives of the *Ascaris* pigments were prepared and were found to be related to each other in the manner characteristic of hæmoglobin derivatives. Such differences as were observed in the mode of their formation could be attributed to the low deoxygenation velocity of the oxyhæmoglobins.

Millikan^{4,5} has shown that interspecific differences in the oxygen affinities of hæmoglobins are the result chiefly of variations in the velocity of association of the pigments with oxygen. He found the dissociation velocities to be of the same order in hæmoglobins having widely different oxygen affinities. The hæmoglobins of *Ascaris* depart from this rule. Oxygen dissociates from the perienteric fluid hæmoglobin 10,000 times, and from the body-wall hæmoglobin 2,500 times more slowly than it does from sheep hæmoglobin.

The ability of *Ascaris* to deoxygenate the hæmoglobin of the body-wall provides evidence that this pigment may have significance as an oxygen carrier at the low tensions of the gas which prevail in the mammalian gut. Laser has shown⁶ that the oxidative enzymic system of the parasite is well adapted to such low tensions of oxygen.

A pigment having similar spectroscopic properties and oxygen relations to that of the perienteric fluid of *Ascaris* was found to occur in the perienteric fluid of *Strongylus* sp. from the horse.

A more detailed account of this work will be published elsewhere.

'Ant Butter'

RECENTLY my father-in-law, M. Platonoff, asked me whether I could give him any information concerning a soft pliable yellow substance which he had found in the nests of wood ants in the forests of the U.S.S.R. The substance was in the form of small lumps and was sought by the peasants, who termed it 'ant butter' (Mourovenue Maaslo). He did not know for what purpose the peasants used it. It is said that bears seek the 'ant butter', and a disturbed ants' nest used to be taken as an indication of their presence.

This substance was undoubtedly the ant 'incense' of Linnaeus. The occurrence of ant 'incense' ('wirak') was first recorded by Linnaeus¹, who described ants collecting resin from juniper bushes and stated that the peasants gathered the pieces of resin from the nests of *Formica rufa* L. and used it as incense, terming it 'wirak'. Wheeler² points out that this is probably derived from the German "Weihrauch", incense. De Geer³ both records and also figures the resin, and states that the wood ants collect it from the pine and fir trees. He says "the ants collect it [the resin] in little masses of irregular form and varying size, of which the colour is sometimes white, sometimes yellow, and often of a dirty white, the

substance is more or less hard except for that which has been amassed fairly recently."

Réaumur⁴ experimented by placing bits of resin in ants' nests, "to see whether they will take on the peculiar quality that makes them resemble myrrh or amber." He also had some correspondence with De Geer on the subject.

Donisthorpe⁵ states that "In Northumberland and Scotland these ants (*Formica rufa*, L.) collect huge quantities of yellow resin—'ant amber'—from the fir trees, I have seen nests full of it."

I have often observed wood ants climbing pine trees in the New Forest (presumably to collect resin) and coming down with their crops full, but have never actually seen the 'ant amber'.

The practice of collecting resin seems to be a widespread habit among the wood ants of the coniferous forests and woods of Europe, but I know of no record of this behaviour from America, nor has anyone yet determined for what purpose, if any, the ants use the resin.

Protein Content of Earthworms

CERTAIN historical events in 1940 interested us in the possible dietetic value of the protein content of earthworms. We found that two Germans¹ and two repetitive Japanese² had shown that all the usual amino-acids produced by hydrolysis of mammalian protein were also obtained from earthworms (*Lumbricus terrestris*), but they gave no quantitative figures of total protein with which we were concerned and which we now report.

Technique. We dealt with common earthworms of a variety of colours and sizes dug from Wiltshire and the London area. At first we analysed worms after keeping them 4–6 days in moss or oatmeal (the scouring process employed by anglers), but found that much 'earth' matter remained, varying from 25 to 45 per cent of the fresh weight. We therefore took large worms, killed them in ethyl alcohol, split and washed them earth-free and dried them roughly to their original moisture. Of these a known weight (sometimes one worm, sometimes two to four) was then desiccated and the nitrogen estimated by Kjeldahl ($P = N \times 6.25$).

	1	2	3	4	5
Fresh worm (cleaned) (gm.)	4.66	8.0	5.0	15.0	26.0
Desiccated (gm.)	0.91	1.66	0.95	2.2	3.7
Water (per cent)	80.4	79.0	81.0	86.0	85.0
Protein, dry worm (per cent)	71.5	62.0	62.0	69.0	71.0
Protein, fresh worm (per cent)	13.95	12.9	11.7	9.9	10.0

Total fat estimation (ether and petroleum ether extracts) on three uncleaned samples were 1.3, 1.0 and 0.76 per cent of fresh weight, equals 1.5 per cent average on the de-earthed worm.

The free sugar or total carbohydrate was not estimated.

RESEARCH ITEMS

Avian Tumour Virus and 'Carrier' Hens

It is stated that losses in poultry flocks due to neoplastic diseases amount to 20 per cent or more, and despite the urgency of the problem of etiology and control of avian cancer, there is little information which can be used as a basis for prevention. Although it is not known whether all spontaneous tumours are virus-induced, most of the successfully transplanted sarcomas were found to be associated with a causative virus. Susceptibility to Rous No. 1 filterable sarcoma is inherited, and resistant birds frequently respond to infection by this virus by the production of no growth or by a small and transient growth. The virus remains latent in these birds for years after clinical recovery from the infection. Fowl-tumour viruses are disseminated about the body of a host bearing a freshly induced filterable tumour and, although such fowls have only a brief reproductive period left, the virus passes to the egg and hence to the offspring of the tumour-host. The laying capacity of the 'carrier' fowls, on the other hand, appears not to be affected, and it would be expected that their immunity would be passed similarly to their eggs. In attempting to find whether these virus 'carriers' might be responsible for the spread of malignant diseases in such flocks, J. G. Carr (*Proc. Roy. Soc. Edin.*, 52, B, 54, 1944) has investigated the neutralizing ability of the eggs of the 'carriers' and of normal hens and has found that 'carriers' lay eggs which contain a considerable amount of virus-neutralizing antibody in the yolk. Virus could not be detected in the egg-embryo or chick from such birds, nor did the 'carriers' infect other birds in the same pen with the sarcoma virus. The fact that no neoplasms developed in a flock which, by careful husbandry, had been raised free from parasites or infectious diseases, suggests the elimination of some factor operating in ordinary flocks.

Feeding Apparatus of Biting and Sucking Insects

Under the above title, R. E. Snodgrass has contributed an important paper in the Smithsonian Miscellaneous Collections (104, No. 7, Oct. 1944). This work is an extension of the same author's previous memoir on the feeding apparatus in biting and disease-carrying flies published in the Smithsonian Miscellaneous Collections for July 1943. The letterpress and illustrations in the last-named paper are included in the new publication, while the additional matter comprises accounts of the feeding organs of Anoplura, Siphonaptera, Thysanoptera and Hemiptera. Dr. Snodgrass's work supplements, and also brings up to date, the accounts given of those organs in present-day text-books. It makes available a thoroughly modern interpretation of the organs of feeding among both biting and sucking insects. For this reason it will be found to be a valuable aid to students and teachers of medical entomology in particular. The general entomologist also cannot afford to pass over this paper since the author gives an entirely new interpretation of the morphology of the mouth-parts in the Siphonaptera. The actual organs used for piercing, it is claimed, are not the mandibles, as almost every authority has maintained for many years past, but are the laciniae of the maxillae. A further point of importance is that the median stylet, almost always regarded as the labrum, is interpreted as being the hypopharynx. It is main-

tained that blood is sucked up through the fine channel in this organ and so reaches the gut. This is interesting, and by no means improbable, re-interpretation of the mouth-parts of Siphonaptera must wait the verdict of future embryological study as a likely means of testing its claims.

Germ Cell Cycle in Trematodes

Recent work by W. W. Cort on reproduction of the intermediate stages of digenetic trematodes supports the germinal lineage hypothesis of multiplication of the cells of the germinal line (*Quart. Rev. Biol.*, 19, No. 4, Dec. 1944). It is a polyembryony by which great numbers of germinal cells are produced from the original zygote. These germinal cells remain distinct from the soma of the germinal sacs (sporocysts and rediae) and come to lie in their body cavities. Finally, the germinal cells form the adult gonads and the polyembryony is succeeded by gametogenesis with the production of haploid spermatozoa and ova. The germinal lineage hypothesis maintains that these gametes are the only cells in the entire life-cycle that have the reduced number of chromosomes. The theory therefore disagrees with the early explanation of Steenstrup (1842), who said that reproduction in sporocysts and rediae was a process of asexual budding, with Grobben (1882) who maintained that it was parthenogenesis, and Woodhead (1931) who described in the Bucephalidae ovaries and testes of sporocysts and rediae and who believed that true bisexual reproduction occurred even in the intermediate stages.

Vitamin C in Drumstick Leaf

Of the many rich natural sources of ascorbic acid, some, such as lucerne, rose hip, blackcurrant and gooseberry, have been successfully processed to yield concentrates which can be used in small quantities to meet human daily requirements of this vitamin. In a communication to the editors, T. B. Panse and A. Sreenivasan, of the Department of Chemical Technology, University of Bombay, now suggest adding the leaf of the drumstick (*Moringa oleifera*) to this list since the leaf by titrimetric estimation contains 900-1,100 mgm. ascorbic acid per 100 gm. Furthermore the leaf provides in addition 100-120 mgm. of β -carotene per 100 gm. and is thus richer in this respect than either lucerne or rose hip. Aqueous extracts of drumstick leaves, if sampled during the pre-flowering stage, are reasonably stable, losing only 25 per cent of their ascorbic acid after three days storage. On the other hand, a powerful oxidase system is apparently developed in the leaves when the tree is in flower, so that larger amounts of the vitamin are lost during the extraction. This is particularly marked with the flowers themselves, the ascorbic acid of which is practically instantaneously destroyed in the aqueous extract.

Physiological Specialization of Oat Stem Rust

Newton and Johnson (*Can. J. Research*, Sec. C, 22, Oct. 1944) have identified twelve physiological races of *Puccinia graminis Avenae* in Canada from 2,586 isolates studied during the period 1921-43. Annual surveys of the prevalence of physiological races during this period show that each year races 1, 2 and 5 have comprised the bulk of the oat stem rust in Canada. The predominance of these races has been greatest in the three Prairie Provinces, where barberry is virtually non-existent. In regions where barberry is present, other races of greater range of pathogenicity have been found more frequently. The

occurrence of such races, however, was sporadic until 1943, in which year races 8, 10 and 11 attained a wide distribution, apparently traceable to wind-borne uredospores from the south. There is evidence that the strains of these races present in 1943 remain in the uredospore stage for much longer periods than do strains of the same races collected in previous years, a fact that may have favoured their spread that year. The role of the barberry in the origination of generally virulent physiological races is discussed. The possibility that such races may also originate by mutation is suggested by spontaneous pathogenic changes that occurred in the greenhouse, in a culture of race 3 that gave rise to several cultures of race 7.

Effect of Stock on Grafted Plants

'A LOVER of planting' in the "Complete Planter and Cyderist" (1685) writes "It's manifest that amongst fruit trees of one kind in the same orchard some shall bear better fruit than any of the rest and it's not known what to impute this excellency to than to the rootstocks they were grafted on". The variability in tree growth and development and in fruit quality is greatly reduced by grafting the trees on to clonal rootstocks vegetatively raised and hence of uniform genetical constitution. Nevertheless, trees grafted on to seedling stocks of varying genetical constitution are often remarkably uniform in character. Especially does this seem to be so under American practice, where trees are generally bench-grafted on to 'root pieces' so that the rootstock does not include any stem piece, and R. H. Sudds and P. C. Marth (*Proc. Amer. Soc. Hort. Sci.*, 42, 326; 1943) find that trees on seedling stocks are almost as uniform over a period of nine years as those on a number of clonal stocks, while E. W. Greve (*ibid.*, 337) in experiments with five varieties of apples on their own roots and on seedling stocks reports no greater variability in the grafted trees than in the 'own rooted' ones.

Theory of the Focault Test

S. C. B. GASCOIGNE has discussed (*Mon. Not. Roy. Astro. Soc.*, 104, 326, 1944) a diffraction theory for the Focault knife-edge test. His paper is highly mathematical, and only a brief summary of it is possible. A short account of the theory of the Focault test is given and then a closed expression for the variation of intensity over the mirror with arbitrary error, not necessarily small compared with λ , when it is tested with a knife-edge, is derived. From the equation giving the disturbance $D(x)$, it is shown how the usual explanation of the knife-edge test follows from the diffraction theory by considering the limit of the equation when $\lambda \rightarrow 0$. Examples are then given of a number of commonly occurring errors. The well-known phenomenon of the appearance of fringes on a mirror with a turned edge is explained, and intensity curves for mirrors with central and zonal errors are computed. Most of the work was carried out during the author's tenure of the Michael E. Baker Scholarship, University of Bristol.

Chain Reactions

THE breaking of chains on the walls of the vessel is one of the most characteristic and essential features of chain reactions and was introduced by Semenoff in 1927 and by Hinshelwood in 1928, its existence being quantitatively proved by Trifonoff in 1929. Since then, many mathematical and experimental memoirs on the subject have appeared. N. N. Semenoff (*Acta Physicochim. U.R.S.S.*, 18, 93, 1943)

has now presented a clear account of the theory in a form convenient for applications, partly because he has himself found difficulty in working out experimental results, and partly because serious errors have been made in mathematical papers by other authors. A careful consideration of the possibility of small values of the chain-breaking probability ϵ is presented, and results for spherical and cylindrical vessels are worked out. The effect of inert gases is also considered, and some attention is given to the action of solid dusts as 'anti-knocks'. It is, of course, quite impossible to summarize a paper of this character, but attention is directed to it as an important contribution to the literature of chain reactions.

Permanent Magnets

THE economic utilization of modern permanent magnets was the subject of a paper read by D. J. Desmond on February 16 before the Institution of Electrical Engineers. In this paper the author first establishes the equation to the demagnetization curve and then proceeds to discuss the uses of permanent magnets in typical pieces of apparatus. The working of the magnet under these various conditions is considered and the useful part of the magnetic energy is calculated, thus introducing a new method by making use of the unit permeance of a circuit. Certain approximations are made in this calculation and the limitations of the simple theory are then discussed. A method is given of designing a magnet in terms of the constants of the iron circuit. Figures are provided for two modern alloys in common use, and curves are plotted for the complete solution to all design problems. The interchangeability of these two alloys is discussed, and it is pointed out that not all the additional energy of the anisotropic alloy can usefully be employed. This is due to the larger curve factor, which reduces the recovery when a demagnetizing force is removed. It is shown that the $(BH)_{\max}$ value is not the criterion of usefulness of a magnet, except in the simplest case, nor is it necessary for the magnet to work at the $(BH)_{\max}$ point.

Radioactivity of Sedimentary Rocks

A RAPID method for the determination of uranium, thorium and potassium in rocks (based on the use of β -ray counters calibrated with radioactive standards) has been devised by R. F. Beers and C. Goodman, and applied to more than three hundred samples of various types of sediments from oil wells drilled through Paleozoic formations (*Bull. Geol. Soc. America*, 55, 1229, 1944). The results indicate that the principal loci of radioactivity are in (a) heavy minerals in sands and sandstones, (b) potash-rich sediments, and (c) sediments of colloidal deposition. It is shown that organic black shales show excellent correlation of uranium content, organic matter, abundance of grades of colloidal size, and a high ratio of thorium to uranium. All these correlations have an important bearing on genetic relationships in petroleum source beds. Goodman's prediction (*J. App. Phys.*, 13, 276, 1942) that petroleum source beds should have high thorium-uranium values has been supported. Evidence is recorded showing that in primary igneous rocks and organic black shales, potassium and uranium increase directly with one another. It is also established that rocks of high uranium and thorium content possess high emanating power, a feature which complicates the technique of the radioactivity measurements.

THE DISPLACEMENT METHOD OF WEIGHING LIVING AQUATIC ORGANISMS

By ASHLEY G. LOWNDES

IN 1927 a method was devised by which living aquatic organisms can be weighed without removing them from their environment. Two accounts of the method were published in 1938^{1,2}, but a much fuller account of the technique was published in 1942³ and 1943⁴. In outline the method is very simple since, in the case of a marine animal such as a prawn, it consists of placing it in a suitable density bottle which is otherwise full of sea water and weighing the whole. The exact volume of the bottle and the density of the sea water are readily obtainable, and it is then only necessary to know the exact volume of the prawn to ascertain its weight.

The exact volume of the prawn can also be obtained. The bottle is filled with sea water and the contents poured into excess of silver nitrate, and the silver halide weighed. The experiment is then repeated, but with the prawn in the bottle. From the weights of the two lots of halide, the volume of the prawn is obtained with considerable accuracy. Alternatively, the sea water can be poured into a standard flask and an aliquot part titrated. The prawn itself is retained by some suitable means and rinsed with a suitable non-halide solution which is at the same time isotonic with the sea water.

In actual practice the technical details are rather laborious, but the method lends itself to extreme accuracy. It has been reviewed in *Nature*⁵; but since the accuracy of the results obtained caused at one time considerable criticism, a full account of the method was submitted to the Director of the National Physical Laboratory, to whom I wish to extend my sincere thanks, and a report obtained from Mr. Verney Stott, who stated that errors should occur in the fourth place of decimals *only*.

Actually the limiting factor does not lie in the technique, but in the accuracy with which it is possible to obtain the density of the sea water in circulation in the aquarium tanks. This could be filtered and the dissolved air driven off by boiling, but the resulting sea water would then no longer represent the real external environment of the organisms.

The method is applicable to freshwater organisms but a rather different technique is necessary. Large crabs and lobsters weighing several pounds have been tackled, as well as nursehounds up to 4 ft. in length. At the other end of the scale, a single specimen of the second larva of the common lobster has been weighed, which amounted to 0.0074 gm., and by taking a large number of specimens such as are obtained from an artificial fertilization of sea-urchins, it is possible to find the density of the various embryonic stages.

Some Applications of the Method. First and foremost, there is the question of analysis, for clearly you can only analyse correctly provided you can first weigh correctly. Usually all analysis has been carried out on air-dried or oven-dried material, and hence many of the results are open to considerable criticism.

Then there is the relationship between the organism and its external environment, or what is known as the *sinking factor*. The impression has been given by some biologists that a marine organism, since it lives in an environment with a density of about 1.03, is

unaffected by gravity. Thus to quote one instance: "Fishes, by *evading gravity*, increase their range of magnitude both above and below that of terrestrial animals"⁶. True, on a *priori* grounds, we might expect that those organisms with the lowest sinking factor would be the most consistent in their swimming or floating habits, but direct measurement shows that no such simple direct relationship exists.

A consideration of density would have prevented many of the existing fallacies from permeating current biological literature to the extent to which they do at present. Thus for years it has been stated and accepted that the common jelly-fish comprises 99 per cent water. This is, of course, clearly impossible since it implies that the remaining 0.2 per cent would have to have a density of 16 or so.

Again, Stokes's Law has been used for trying to find the density of such diverse material as the bit of a squashed egg of a sea-urchin, and a narcotized Calanoid or a Cladoceran the surface of which is practically covered with spines, yet some of the first conditions for the application of the law are that the particles must be smooth and spherical, and the radius known or at least measurable.

If, on the other hand, we can weigh accurately a living Calanoid and obtain its density, and then find its rate of sinking through unadulterated sea water, we should be able to get a close approximation to the amount of energy needed to keep such an animal near the surface, or possibly the energy expended during rapid swimming movements.

Finally, there is the question of the resolution of forces about the centre of gravity. If the tissues are more or less homogeneous and arranged more or less symmetrically about a point, that point will constitute the centre of gravity of the organism. But, if such an organism is situated in an external environment the density of which is equal to the density of the whole organism, then there can be no *functional* centre of gravity. This seldom occurs in actual fact but many of the teleost fishes with large central swim-bladders approximate closely to it.

Embryology. Embryologists still talk about the high density of 'yolk' and its effect on segmentation. The density of the yolk of the hen's egg is, however, 1.025, while that of the dogfish egg is 1.1. Thus the density of the yolk in the one far exceeds the density of protoplasm, while in the other it is considerably below it, yet in both cases the segmentation is meroblastic and this is always attributed to the presence of the yolk. Alternatively, the ova of *Echinus* are small and have a low density and very little yolk, while the ova of the spider crab *Mancusquado* are very much larger and have a density greater than 1.1, yet in both cases the segmentation is holoblastic and equal, or at any rate it appears to be so.

Evolution. The real interest of the method, however, lies in the light that it may possibly throw on the primary cause of evolution. Almost ever since the publication of the "Origin of Species", most biologists seem to have regarded evolution as exclusively a biological process, with most disastrous effects on the study of biology itself. It is true that Herbert Spencer was careful to describe the origin of organisms and the increase in complexity of tissues as *organic evolution*, but his example has certainly not been followed recently. Moreover, the still worse error of regarding natural selection or the struggle for existence between individuals as one of the primary causes of organic evolution is still rampant. Though natural selection has now been cleared of much of

uperfluous material and constitutes a sound and mathematical concept, chiefly owing to the work of A. Fisher, yet, whatever the importance of the process within organic evolution itself, it was not a primary cause

Clearly cosmic or inorganic evolution must have been at work long before organic evolution started, and the primary cause of organic evolution is to be sought for within the cause of inorganic evolution. It is true that the origin of the universe or even of the solar system is still a much debated question, but no scientific theory yet put forward disregards the law of gravitation, and most include either the concept of maximum entropy or of thermodynamic potential. Clearly none of these concepts is applicable to organisms or tissues of unknown weight or density. The very elementary theoretical outcome of this view may be cited briefly. Without disregarding the fact that there may be no real distinction between the living and non-living in the initial stages, we are justified in assuming that the first *free-swimming* organisms consisted of protoplasm and existed near the surface of water. Since, however, the density of protoplasm must always exceed that of the water constituting its external environment, the first struggle for existence must have been influenced by gravity and not primarily by competition between individuals. It would appear, therefore, that the accurate determination of weight and density is of fundamental importance for an accurate study of aquatic organisms.

THE HORSE-CHESTNUT TREE (*AESCULUS HIPPOCASTANUM*)

By ALEXANDER L. HOWARD

"Oh! there the chestnuts, summer through,
Beside the river make for you
A tunnel of green gloom, and sleep
Deeply above"

RUPERT BROOKE

THE horse-chestnut tree is not indigenous to Great Britain but was introduced in the middle of the sixteenth century, there is some doubt as to its origin, but the general opinion is that it was a native of the Balkan mountains, or perhaps that it was introduced there from Iran, northern India or Tibet. Gerrard speaks of the first tree being heard of in 1579, and from this date it became generally planted throughout western Europe, especially in Ireland, Sicily and Corsica. In the most favourable circumstances it may attain a height of about 20 ft, with a girth of 18 ft, and in Ireland Elwes mentions a tree at Woodstock, Kilkenny, which was 3 ft in height and 18 ft. 1 in in girth. The tree is well known to men, women and children, the former principally for the beauty of its flowers in the early summer, and the latter who wait impatiently for the autumn when they can throw sticks at the branches to dislodge the fruits which contain the seeds or "conkers".

The horse-chestnut (*Aesculus hippocastanum*) is often mistakenly confused with the sweet-chestnut (*Castanea sativa*) to which it is not related either in fashion or family. C. A. Johns says that the origin of the name is in doubt. "The name *Aesculus*, from *esca*, food, was applied originally to a species of Oak, which, according to Pliny, was highly prized for its acorns, but how it came to be transferred to the Horse Chestnut is very uncertain, perhaps, as Loudon suggests, it was given ironically because its nuts, which are unfit for food, bear a great resemblance externally to those of the Spanish Chestnut *Hippocastanum* is a translation of its modern name, which was given 'from its curing horses broken-winded and other cattle of coughs'" (Evelyn)

Pliny, according to the translation by Dr Philemon Holland, does not mention horse-chestnut, but he describes what he calls *Esculus*, terming it oak. This does not apply to the oak but fits the horse-chestnut. In his time the mountains of Greece abounded with these trees, and it is thought that this was its native habitat. It was introduced and freely planted in Sardinia, Sicily, and Corsica, and Pliny refers to what he calls "the Sardinian nut". Whether by this name he was speaking of the sweet-chestnut or the horse-chestnut is not clear, but it is probable that he was referring to the sweet-chestnut. It seems evident that in his time the tree was valued for its fruit but not for its timber. He says

"The best mast (nut) and the biggest is the acorne growing upon the common Oke, next to it is that of the *Esculus*, as for that of the Robur it is but small. The cernus carrieth a mast unpleasant to the eye, and rough to be handled, for clad it is with a cup beset with sharpe prick like to the Chestnut tree

We entitle Chestnuts also by the name of Nuts, although indeed they are more aptly to be called a kind of Mast. This fruit whatever it be, is enclosed within a huske, and the same defended and armed all over with a ramper and palisade (as it were) of sharpe pricks like the skin of an Urchin, whereas the Acorne and other Mast is but half covered, and that defence in them is begun only. And certes, a wonderful matter it is, that we set little store by this fruit, which Nature is so careful to hide and defend. Under one of these husks ye shall find sometime three Chestnuts, and those having certain tough pills or shells very pliable. But the skin or filme within, and which is next to the bodie or substance of the fruit, unless it bee pulled off and taken away, marroth the tast of it, like as it doth also in other nut kernels. Chestnuts, if they be rosted, are better and more pleasant meat than otherwise. They use also to grind them to meale, and thereof is made a kind of bread that poore women for hunger will eat. The first Chestnuts were knowne to grow about Sardis and from thence were brought and therefore the Greeks call them Sardinian nuts."

It is impossible to decide for certain whether he was speaking of the sweet-chestnut or the horse-chestnut, but it seems probable that although his description would apply equally to the nuts of either tree, he must have been referring to the former.

At the time of John Evelyn it became fashionable to plant the horse-chestnut in avenues, and many famous examples dating from this time can still be seen in different parts of the British Isles—as well as on the Continent, in private and public parks and gardens. In this way the chestnut shows its full beauty and dignity at all seasons of the year, but specially when its candle-like flowers are in full bloom. One of the most famous chestnut avenues in England is at Bushey Park, Hampton Court, which is visited year by year by many people on Chestnut Sunday.

However it is situated, the horse-chestnut is the

first of our trees to clothe itself with green leaves, which are different in shape from those of our other forest trees, having five to seven leaflets, 4-9 in. long, and brilliant light green in early spring, deepening to a heavy darker shade and turning to golden yellow before they fall in early autumn.

The bark is smooth of a greenish-brown colour, and the crown generally becomes pyramidal in shape. Sometimes the branches droop, and in cases dig into the ground all round the base of the tree, whence they take root and spring up again, often attaining a much increased girth in the upward growth than that proceeding from the tree in the downward bend. A remarkable tree of this habit is in vigorous health at Hawkhurst Moor, with a height of about 90 ft., and covering the ground to a circumference of 285 ft.

The yellow horse-chestnut (*Aesculus octandra*) was first introduced into England in 1764. The red horse-chestnut (*Ae. carnea*) was, according to Elwes, first introduced from Germany in 1818. Both may be seen in almost every garden and park, especially around London and other cities. Neither of these trees attains the dimensions of the common horse-chestnut (*Ae. hippocastanum*).

Ae. pavia, a shrub bearing a red flower, is referred to by Elwes, who says "it closely resembles *Aesculus octandra*" and supposed to have produced with *Ae. hippocastanum* the hybrid *Ae. carnea*. Loudon describes this as "The Pavia, or smooth-fruited Horse-chestnut tree" and also mentions *P. rubra*, but the whole subject is so confused that it is difficult, if not impossible, to state accurately the botanical variations.

Both the horse-chestnut and the sweet-chestnut, for some unexplained reason, are subject to spiral growth in the British Isles. During the War of 1914-18, the subject of spiral growth came very much to the fore, as apparently sitka spruce (*Picea sitchensis*) imported from British Columbia was found to carry this defect more than any other tree for which there was an equal demand. Inquiry into the subject brought suggestions, one of which was that it was a hereditary feature. Although this may be possible, I am more inclined to think that spiral growth is caused by the situation of the tree and its relation to the sun and wind. In Hyde Park, in the triangular piece of ground between the Magazine and the Epstein statue, by the Serpentine, there are twenty-four horse-chestnut trees, all but two of which show spiral growth, a number proportionately much greater than in any other part of the Park. This site must be subject to varying winds from different quarters, while the rays of the sun may influence the direction of the growth. At the same time, it is strange that one particular tree should be subject to more spiral growth than another—a subject well worth inquiry.

About 1920, shipments arrived in London, and probably Paris, Hamburg, and Rotterdam, of Japanese horse-chestnut (*Aesculus turbinata*—the Japanese name for which is 'Tochi-noki'). These shipments consisted of large-sized slabs, or flitches and planks. The wood was similar in colour and texture to that grown in England, but mainly consisted of highly figured wood, rich in roe and splash-mottle, some bright and clean, while other was streaked with black marks—denoting incipient decay. All this timber was equally sound and good, while that streaked with black was particularly decorative, and was greatly in demand for art furniture in which it realized high values.

Speaking of the British variety, Elwes mistakenly says:

"The wood of the Horse Chestnut is one of the poorest and least valuable we have, on account of its softness and want of strength and durability. Though it has a fine close and even grain, white or yellowish-white colour, and is not liable to twist or warp so much as most woods, it does not cut cleanly."

Elwes cannot have known the many purposes for which chestnut has been used.

Quoting from "Timbers of the World":

"If the tree be cut down early in winter, promptly sawn into boards, etc., and carefully stored, wood of extreme whiteness may be obtained. If, however, the trunks are felled later in winter, or are allowed to lie for any length of time the wood assumes a yellowish-brown tint. It is of moderate weight, soft fine-grained, but perishable, used for making soap-bowls, brush-backs, in turnery, and occasionally for veneers. Even with the development which have occurred since the war (1914-1918), supplies of horse chestnut are not sufficiently valued or appreciated. In Southern Europe it is said to have been used for fruit-storing shelves, the porous nature of the wood absorbing the moisture from the fruit, the preservation of which is thereby assisted."

Besides its use for gunpowder and charcoal, this timber is most valuable for furniture and works of decorative art, for which purpose it has been by far too little appreciated.

STATISTICS IN GOVERNMENT DEPARTMENTS

A MEMORANDUM on the Post-War Organization of Statistics in Government Departments, which has been prepared by the Institution of Professional Civil Servants for submission to the Treasury, draws largely on material in the Memorandum on Official Statistics issued by the Royal Statistical Society with the recommendations of which the Institution to a considerable extent agrees, apart from certain proposals with regard to the structure of the statistics service and the status of its officers. The Institution's own proposals are set out under five headings. First, with regard to the functions of a statistical service, it is considered that the work of the statistical service should be an integral part of the administration, including such public functions as the collection, presentation and publication of a continuous series of statistics relating to the economic and social condition of the nation, the interpretation and enlargement for publication of material already covered in part by existing statistics, together with explorations into fields not hitherto covered, so as to provide industry and trade with information which by its nature can only be collected through the agency of the Government, and research into the statistical aspects of social questions. One internal function should be provision of the pre-requisites of policy formation, and the memorandum claims that the statistician, in providing material on the quantitative aspects of a problem, should be called upon to play his part in deciding how things planned for the future are to be attained.

Next, with regard to grades, salary, promotion and superannuation of statistical staff, the Institution urges that there should be only two classes of statistician, a principal statistician class, with career value comparable with that of the administrative class of the Civil Service, and an executive

statistician class, working normally under the direction of members of the principal class and with career value comparable with that of the executive class. Superannuation should be provided on terms comparable with those available to the rest of the Civil Service, and in addition to facilities for post-graduate training and for opportunities for widening experience by seconding for limited periods to statistical posts outside the Government service, the institution emphasizes the desirability of transfer of statisticians to administrative posts, as well as of transfer between departments and with the Central Statistical Office. The views of the Royal Statistical Society on the value of mechanical aids are endorsed.

With regard to the qualifications and recruitment of statistical staff, the memorandum welcomes the scheme to set up a certificate and diploma in statistics proposed by the Royal Statistical Society, and although the syllabus appears to demand a rather higher standard of mathematical statistics than would in general be required for entry into Government service, possession of the diploma is suggested as an alternative qualification to a university degree with first- or second-class honours in the relevant subject, including statistics, for eligibility for appointment to the principal statistician class. For the executive statistician class, the higher school certificate with distinction in statistics, or the Royal Statistical Society's certificate is suggested. A central recruiting body for statistical officers should certify the candidate's eligibility for appointment, and appointments should be made by a selection board from eligible candidates on the basis of interview, the Board including representatives of the central recruiting body, the Establishment Department, the Institution of Professional Civil Servants and the head of the statistical section of the department concerned. These conditions are not intended to apply to existing members of the Government statistical service or to persons who have done outstanding statistical work elsewhere.

With regard to the transition to the post-war period, sufficient of the existing personnel should be retained to ensure the immediate establishment of a comprehensive statistical service envisaged, and an immediate decision on the questions of post-war organization, recruitment, salaries and promotion is a matter of urgency. With regard to statistical material, it is important to ensure that existing collections and compilations are preserved, and pressure from commercial firms in favour of discontinuing the making of returns necessary for statistical continuity should be resisted. Statistical branches should collect basic data from the source.

With regard to the relation between statistical branches and the Central Statistical Office, the institution examined the suggestion for a Government statisticians' department, but decided that the type of organization recommended by the Royal Statistical Society would give a more efficient statistical service, and accepted the recommendations of the Society's memorandum with regard to the functions of the Central Statistical Office. That Office should maintain a central library and records office staffed by people competent to give advice. It should maintain a full record of confidential statistics compiled by all the various Government departments, and available to authorized persons in the Government service. The library would also be the depository for statistical records of Government departments which close down.

TOXIC SPRAY SUBSTANCES AND PLANT GROWTH

ONE result of the continued use of sprays containing toxic inorganic constituents may be the accumulation in the soil of substances deleterious to plant growth. Of practical interest, therefore, are experiments described by N. F. Childers¹, who found that the presence of sodium arsenate in the soil had a stimulating effect on 'Delicious' apple seedlings when the concentration was not more than 20 parts per million. Between 60 and 160 parts per million, toxic effects were apparent, and if the concentration was more than 100 parts per million the seedlings died. Equivalent amounts of arsenic in the form of lead arsenate were less toxic, and lead chloride even at 160 parts per million exerted no deleterious effect. More carefully controlled experiments with plants in gravel culture showed that 20 parts of arsenic per million of culture solution stimulated the growth of apples and of rye but depressed the growth of grapes. Both apples and grapes were tolerant of 200 parts of lead per million of solution and both showed a progressive decrease in growth as the copper content of the solution rose from 10 to 30 parts per million.

Different fruits show differing tolerance of arsenic, but R. C. Linder² reports that peaches are especially susceptible, and if the arsenic content of the leaves exceeds 2 parts per million of dry matter, marginal and interveinal burning and shot-holing of the leaves occur, with, in severe cases, defoliation. Apricots show a similar effect, but plums, pears and apples are more resistant, and plum foliage containing as much as 13 parts of arsenic per million of dry matter appeared healthy.

² *Proc. Amer. Soc. Hort. Sci.*, **42**, 275 (1943).

FORTHCOMING EVENTS

Saturday, April 28

NUTRITION SOCIETY (joint meeting with the BIOCHEMICAL SOCIETY) (at the London School of Hygiene, Keppel Street, Gower Street, London, W.C.1), at 11 a.m.—Discussion on "The Vitamin-B Complex".

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (joint meeting with the MIDLAND BRANCH) (at the University, Edmund Street, Birmingham), at 2.30 p.m.—Dr. H. Kuhn "Atomic and Molecular Beams".

Sunday, April 29

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N.W.3), at 11.30 a.m.—Dr. B. Burzryn "On Recent Applications of Thermo-setting Resins on Paper and Textiles".

Monday, April 30

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Sir Frank Smith, G.C.B., F.R.S. "Chemicals from Petroleum" (Cantor Lectures, 3).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Sir Amos Ayre, K.B.E. "An Approximate and Simple Formula concerning Four-Bladed Propellers of Single-Screw Cargo Ships".

Tuesday, May 1

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield 1), at 6.30 p.m.—Dr. N. P. Ingles "Some Views on Materials of Construction and their Fabrication, in the Light of Present Research and Likely Requirements".

INSTITUTION OF ELECTRICAL ENGINEERS (LONDON STUDENTS' SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Discussion on the Report on "Education and Training for Engineers" and a subsequent Report on "Part-time Further Education".

Wednesday, May 2

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. G. W. Osborn "A Rapid and Simple Method for the Determination of Calcium in presence of Strontium and Barium", Mr. W. B. Wragge "Lead Printing" of Ferrous and Non-Ferrous

Metals", Mr E Collins "Reaction of Diazotised *p*-Nitraniline with Phenols, Detection of Tricresyl Phosphate in Edible Oil" Dr A J Henry "A Simple Apparatus for Handling Standard Solutions of Bromine in Potassium Bromide"

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m — Mr N Lea "Notes on the Stabilities of L C Oscillators"

Thursday, May 3

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (PHYSICAL METHODS GROUP) (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 3 p m — Dr H W Thompson "Infra-red Spectrography in relation to Chemical Analysis"

THE BEDSON CLUB (King's College, Newcastle-upon-Tyne, 2), at 5 30 p m — Dr U R Evans "The Prevention of Metallic Corrosion, by means of Soluble Inhibitors" (Bedson Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m — Mr R T Lythall "Excess-Current Protection by H R C Fuses on Medium-Voltage Circuits", Mr A G Shreve and Mr P J Shipton "Excess-Current Protection by Overcurrent Relays on Medium-Voltage Circuits"

Friday, May 4

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p m — Sir William Halcrow "Tidal Power"

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION), (at Savoy Place, Victoria Embankment, London, W C 2), at 5 30 p m — Mr G F Shotton "Meter and Instrument Jewels and Pivots"

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W 1), at 6 p m — H G Dines "Mining Geology of Cornwall and Devon"

Saturday, May 5

AMATEUR ENTOMOLOGISTS' SOCIETY (at Buckingham Gate Central Schools, Wilfred Street, Victoria, London, S W 1), at 2 p m — Exhibition of Entomological Apparatus and Technique

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

BOROUGH ANALYST—The Town Clerk, Town Clerk's Office, Civic Centre, Southampton (endorsed 'Appointment of Borough Analyst') (May 4)

HISTOLOGICAL TECHNICIAN FOR THE DEPARTMENT OF ANATOMY—The Secretary and Registrar, The University, Bristol (May 4)

SOIL CHEMIST—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (May 7)

RESEARCH PHYSICIST for advanced experimental work in connexion with Electron Tube Research and Development, and an Officer for Microwave Crystal Development work on the staff of the Division of Radiophysics, Sydney—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W C 2 (May 11)

LECTURESHIP IN MECHANICAL ENGINEERING—The Principal, Heriot-Watt College, Edinburgh (May 14)

ASSISTANT INSPECTOR (male) OF FISHERIES in the Department of Agriculture—The Secretary, 45 Upper O'Connell, Street, Dublin (May 18)

ASSISTANT IN THE BURSAR'S OFFICE—The Bursar, Bedford College, Regent's Park, London, N W 1

ASSISTANT PHYSICIST to the Deep X-Ray Therapy and Radium Centre—Dr H Canwarden, Medical Superintendent, Warren Road Hospital, Guildford, Surrey

LECTURER IN BACTERIOLOGY to students preparing for the National Diploma in Dairying—The Principal, Studley Agricultural College, Studley, Warwickshire

LABORATORY STEWARD FOR PHYSIOLOGICAL LABORATORY—St Mary's Hospital Medical School, London, W 2

SCIENCE AND PROGRESS IN INDIA

THE extent to which the welfare, prosperity and, indeed, the very existence of a nation depend on scientific research and on the application of scientific knowledge has been brought home to everyone during the present War. Their supreme importance was fortunately realized in time in Great Britain, and between 1939 and 1941 arrangements were made between the United Kingdom, the Dominions and the United States for close co-operation in scientific research and the full interchange of scientific and technical information in all matters connected with the War. As a consequence, there are now scientific missions or representatives of the Dominions and the United States in London. The United Kingdom has a scientific representative at Ottawa, and there is at Washington a British Central Scientific Office that acts jointly for the United Kingdom and the Dominions in maintaining a scientific liaison with the United States. In addition, many special missions have been continually at work in all these countries. An attempt in 1941 to bring India into this picture was, however, unfortunately unsuccessful, as the need of this scientific and industrial collaboration was not then recognized in that country.

To help the continuance of such collaboration after the War, when problems of reconstruction and development for the betterment of the life of the people of the world will arise, the Royal Society in 1941 took the opportunity of the presence in London of scientific representatives of the Dominions to set up a British Commonwealth Science Committee to consider how collaboration in scientific matters throughout the Commonwealth and Empire could be made closer, and in the absence of any Indian men of science in London, the secretary of the Education Department at India House attended. One result of the report of this Committee* is that it is now proposed to call after the War an Imperial Scientific Conference to which scientific representatives of the United Kingdom, India, the Dominions and the Colonies will be invited.

When the Government of India became aware of these activities and of the feeling among British men of science that their Indian colleagues should be taking part, an invitation was sent by the Viceroy, through the Secretary of State for India, to the president of the Royal Society, for Prof. A V Hill to go to India as the representative of the Society, in order to discuss the organization of scientific and industrial research as a part of the Indian post-war reconstruction plan, and also current research problems, with visits to universities and other research centres. The Royal Society agreed to the proposal, and Prof Hill spent from November 1943 to April 1944 in a tour of Indian centres of work connected with science, medicine and technology.

The results of his discussions, visits and contacts with Indian science, industry, medicine and official circles have now been published in a document of

* British Commonwealth Science Committee. (Royal Society, Burlington House, London, W 1 1943)

University College
Physics
23 Upper Circular Road

great importance, entitled "Scientific Research in India". A digest of the report, section by section, appears elsewhere in this issue of *Nature* (p. 532). This document, of which the preface is dated August 14, 1944, is all the more important because everywhere he went Prof Hill was welcomed with the utmost cordiality and given the freest access to information as a representative of the Royal Society and of British science. As a result of his tour, Prof Hill is convinced that there is no difficulty in the way of full and friendly co-operation between India and Great Britain in the scientific, medical and technical fields. Everywhere the emphatic opinion was expressed that one of the most important needs to-day of Indian science, medicine and technology is better facilities to send the ablest young Indians abroad, particularly to the United Kingdom, for advanced and postgraduate study, for work experience, and for training in research.

In order to understand the implications of this report, it is desirable to know something of the history of the development of the present scientific background in India. This development has followed two parallel lines, official and non-official, each beginning towards the end of the eighteenth century in Calcutta, which was the capital city of the East India Company and later (from 1858) of the Government of India under the Crown, until the removal of the capital to New Delhi in December 1911 as a result of the visit of the King-Emperor to India.

The official line began with the appointment of such officials as the Superintendent of the Botanical Gardens, Sibpur (1788), the Assay Master at the Calcutta Mint (1792), and a Government geologist (1818), and the establishment of the Trigonometrical Survey (1800), and of several astronomical and meteorological observatories (1792-1824), leading ultimately to the formation of the modern survey departments, the Geological Survey (1851), the Meteorological (1875), Survey of India (1878), and the Botanical Survey (1889). This was followed by provision for the applied sciences, mainly in the form of research institutes, for example, agriculture (1885-1903), veterinary (1890-1925), forests (1906), medical (1906), and public health and hygiene (1934). Another phase of official provision has been through the institution of universities, in Bombay, Calcutta and Madras, all dating from 1857, the year of outbreak of the Mutiny, the Punjab (1882), and Allahabad (1887), with several others founded during the present century. The Indian Institute of Science at Bangalore may be conveniently mentioned here, though it owes its inception to the munificence of the Tata family, supplemented by Government aid. Private bequests have, of course, also played a part in the development of the universities of India.

The non-official line of development began with the foundation of the Asiatic Society (now the Royal Asiatic Society of Bengal) by Sir William Jones in 1784. From its activities has sprung the larger part of non-official scientific activity in India (including a portion of the development along the official line), not to mention all its own work for literature, history, archaeology and philology. In addition, the Indian

Museum, Calcutta (1866) was based originally on the collections of the Asiatic Society, the official Zoological Survey of India (1916) is a descendant of the zoological section of this Museum. The Asiatic Society must also be regarded as the mother of the Indian Science Congress Association, which held its first meeting in 1914, and, as Prof Hill remarks, the grandmother of the National Institute of Sciences of India, founded by the Indian Science Congress in 1934.

Besides the Royal Asiatic Society, there are now two other academies claiming national scope, namely: (a) the United Provinces Academy of Sciences, founded at Allahabad in 1930, renamed the National Academy of Sciences, India, in 1936, and (b) the Indian Academy of Sciences, founded at Bangalore in 1934.

The growth of scientific activity in India has led also to the formation of a number of specialist all-India societies mainly with their headquarters in Calcutta, for example, mining and geology (1906), mathematics (1907), engineering (1921), botany (1921), chemistry (1924), physics (1934), soil science (1934), and physiology (1934).

From the dates of formation of these non-official academies and specialist societies, it will be realized that during the present century there has been an astonishing efflorescence of science in India as compared with the nineteenth century. This is of course partly due to the growth both in number and stature of the Indian universities, and is best recognized from the wonderful success of the Indian Science Congress, which with the help of a deputation from the British Association, celebrated its twenty-fifth birthday in 1938. This Congress moves annually from centre to centre on the model of the British Association and is now commonly attended by upwards of a thousand members of all grades, this is all the more surprising in view of the sub-continental size of India and the distances that many of the members must travel in order to attend. This annual assembly of scientific workers is also the venue of the annual meetings of most of the all-India scientific societies, as well as of the National Institute of Sciences of India.

The foregoing summary is but a brief outline of the official and non-official provision for science up to the time of Prof Hill's visit. It must be remarked, however, that there has been a marked difference in this century between the rates of growth along the official and the non-official lines. Whereas, on the non-official side, growth once it began was on the whole continuously progressive, the same cannot be said of the official side. It is notorious that official science is subject to severe setbacks when official finances become straitened. During this century there have been two periods of such retrenchment. The first was in 1925, when the Incheape Committee from Great Britain recommended some measure of retrenchment, and the second was in 1931 when, on the recommendation of an Indian Retrenchment Committee, widespread and disastrous curtailment was effected throughout the Government scientific services. The special selection of science for such slaughter showed how little the Government of India understood or valued such work, and it cannot be

nied that in consequence India faced the onset of the present War much worse equipped scientifically than would otherwise have been the case. The change is heart shown by the Government of India in now turning for the help of British science to strengthen Indian science, both academic and applied, is thus all the more to be welcomed. The sad thought is that it has required the impact of war to produce this change.

Although it was not until 1943 that this call for British scientific advice was made, the Government of India had in fact, in 1940, already taken a notable step with the foundation of the Board of Scientific and Industrial Research, which may be regarded as the Indian equivalent of the Department of Scientific and Industrial Research in Britain, and that the Government of India now takes seriously the need for scientific research is shown by the fact that special provision was made in the Budget of 1944 for fuel research and glass research, and for national laboratories for physics, chemistry and metallurgy, so the Government of India gladly accepted the invitation of the British Government, sponsored by the Royal Society, to send a deputation of leading Indian men of science to Great Britain in the autumn of the same year. The members of this deputation are given every privilege and facility to enable them to visit centres of scientific and industrial research in Britain and to make contact with the leading industrial enterprises likely to be helpful to India, and afterwards they went to the United States to make similar contacts there.

The above recital of the past and continuing growth of science in India sounds impressive, so long as India is pictured as one country and its scale is forgotten, but it must be remembered that India is nearly as large as the whole of Europe without the U.S.S.R., and that it has a population approaching 400 millions. Against a background of this magnitude, India's scientific provision is, of course, very small indeed, and there is, as Prof. Hill saw, the need in all directions for great expansion in scientific, medical, and industrial research. This is required for three principal reasons: (1) the improvement of the health of the population, (2) the adequate feeding and employment of this enormous population, which is bound to go on expanding rapidly, (3) the provision of adequate defence forces with modern equipment. Let us consider further the third reason, though only in general terms. Prof. Hill rightly points out that if India wishes to attain national stature, she must be prepared to provide her own defence forces for the future, without reliance on the British Treasury. Thinking of what this may mean has been given by the present War. In the past, when the cost of a portion of the Forces in India has been defrayed by Britain, on the ground that that part was not maintained for purely Indian reasons, the unofficial members of the Indian Legislative Assembly have persistently opposed the provisions of the military portion of the Budget for the maintenance of the garrison. This has appeared as a high proportion of the Central Budget, sometimes as much as 40 per cent, but there are also the budgets of some ten

provincial Governments, none of which pays a penny towards defence. If the totals of these be added to the central total, the provision for defence is seen to be a much smaller proportion of India's total income. This should be emphasized, for in the future, as Prof. Hill sees it, there must be a greatly increased expenditure on defence, so as to enable the equipment of Indian Forces, land, air and sea, to keep abreast of that of other countries on the modern elaborate and costly scale. In addition, to ensure a high quality for this equipment, it will be necessary to maintain an adequately appointed scientific research organization within or in affiliation with the Defence Department, Prof. Hill proposes a War Research Board for this purpose.

How is all this expansion—medical, agricultural and defence—to be financed? Only by a great expansion and improvement of India's basic industry, agriculture, and by a great growth of her existing industries, with the addition of new industries. The Bombay plan of a group of Indian industrialists was proposed for such purposes, and even though its very magnitude may seem visionary, yet some such plan must be implemented, at least in part. The Government of India has accordingly now taken this task in hand, and, following Prof. Hill's visit, has formed a new Department, that of Planning and Development, with, for its first member, Sir Ardeshr Dalal, former managing director of the Tata Iron and Steel Co. and one of the authors of the Bombay plan.

The greatest weakness in the Government of India in respect of scientific activities is that responsibility for it is scattered instead of concentrated. For example, meteorology is under the Department of Posts and Air, geological survey under Labour, the Survey of India, and the Botanical and Zoological Surveys, under Education, Health and Lands, which also controls medical and agricultural research in part. What is needed is that all these scientific activities should be grouped under one member of Government, for which the new Member for Production and Development seems appropriate.

Prof. Hill's recommendation is, therefore, that there should be a Central Organization for Scientific Research working under the Honorable Member for Planning and Development, divided into six research boards: medical, agricultural, industrial, surveys and natural resources, engineering, and war. He makes suggestions for the constitution of these boards, and for each of these branches of activity he proposes a director of research, who would be secretary and principal administrator of his own board, and a member *ex-officio* of each of the other boards. The responsibility of these six directors would be for directing, organizing, initiating and co-ordinating research, on a nation-wide scale, so far as constitutional considerations allowed, each in his respective field.

Between these boards jointly there would be a Research Grants Committee, and a Research Studentships Committee. There would also be a Scientific Consultative Committee to advise the Member for Planning and Development on general policy in relation to research, consisting of the six directors of

research, together with six other distinguished men of science

In advocating this general principle of bringing research into a single organization, Prof Hill points out that this would still leave the Departments of the Government of India free to make their own arrangements for applying the results of research to the practical problems they have to face. From this point of view, Prof Hill regards these other Departments of the Government of India as the 'user' Departments, which, charged with the responsibility of applying the results of research, could set up development or improvement councils, with a liaison with the corresponding research boards. Then, to ensure that development as well as research is co-ordinated at a high level, Prof Hill would set up under the Member for Planning and Development, as an opposite number to the Scientific Consultative Committee, a Development Consultative Council.

If the Government of India acts on Prof Hill's report, as there is every reason to suppose it will, then India will be provided with a co-ordinating and initiating organization for research in the six fundamentally important fields outlined by Prof Hill, an organization that should help materially the improvement of the health of India, the necessary expansion of its agricultural resources, and the expansion of its industries, with a resultant higher level of health and of the employment that is so necessary to produce the greatly increased revenue needed for the general welfare, including the defence of India.

Proposals for the expansion of Indian science and industry cannot, however, be implemented unless men, both in numbers and in quality, are forthcoming to carry them out. India's present educational equipment, including that of the universities, technical colleges, and research institutes, is quite inadequate for the purpose. Consequently, pending a great improvement in educational and technical facilities in India, large numbers of graduate students will have to be sent abroad at Government expense for postgraduate training, both scientific and technical. It is understood that the Government of India is making arrangements for this, and that we may expect a considerable number of such students to arrive in Britain this year. Conversely, it will probably be found necessary, as a temporary measure, for India to import from abroad a considerable number of highly qualified men to help in the reorganization of teaching and training in India. These remarks are made without any reflexion on the professors and other teachers in India, who have done splendid work with the insufficient facilities at their disposal, as must be evident to anyone who contemplates the astonishing success of the Indian Science Congress, of which mention has already been made, or the fact that several Indians have been elected to the fellowship of the Royal Society.

The organization for research proposed by Prof Hill and outlined above will, of course, if adopted, be an official scheme for the co-ordination of scientific research in India, and when carried out it will have to be regarded as a sudden burgeoning on the official

line of development, incidentally co-ordinating, so as possible, activities on the non-official line of growth. There will, however, remain the non-official activities that find their expression in the special scientific societies, in the academies, in the Indian Science Congress Association, and in the National Institute of Sciences of India. These non-official developments must be encouraged by Government and helped financially, while still remaining free. Nevertheless, these non-official activities also need co-ordinating. Prof Hill refers to the fact that Indian men of science have advocated strongly the formation of a National Research Council, and to the four resolutions on this matter passed by the National Institute of Sciences in 1944. Without enumerating these resolutions, it may be said that they were designed to give Indian science and Indian scientists a greater and more appropriate part in national affairs. Prof Hill holds that his proposals are designed to meet the same needs and difficulties as the proposals of the National Institute, and that they will be acceptable to that body. But although Prof Hill's proposals may render unnecessary the formation of a National Research Council formally so named, they do not remove the necessity for a co-ordinating organization for Indian non-official scientific bodies. The National Institute of Sciences of India was, of course, formed for this very purpose, as Prof Hill recognizes, and in fact he expresses the hope that formal recognition may be given to its position by the Government, for example, by the grant of a Royal Charter such as the Royal Society and the British Academy have.

Incidentally, Prof Hill comments on the 'original' name of the National Institute, recognizing, however, that the name chosen was due to a compromise at the time of foundation. The name is, however, not so odd as it sounds, for the organizing committee, selecting this name, was influenced by the example of the Institute of France, which is a co-ordinating body for the five French academies, both of sciences and letters, and which in an earlier stage of existence was called the National Institute of Sciences and Arts. As the Indian body was to co-ordinate scientific bodies only, it was named the National Institute of Sciences of India, leaving the field open for its foundation at a later date, for example, by the Royal Asiatic Society of Bengal (which is an academy both science and letters), of a National Institute of Letters to co-ordinate the activities of academies of letters in India, with perhaps also the formation of a National Institute of Arts co-ordinating the activities of academies of arts in India. Once this has happened, the need may arise for co-ordinating the three national institutes into a National Institute of Arts, Letters and Sciences of India as 'The Institute of India', equivalent to the Institute of France in comprehensive scope. The foundation of the National Institute of Sciences of India, although on an all-India basis, aroused a certain amount of provincial jealousy at the time of foundation, so that the present location of its office in the building of its 'grandmother', the Royal Asiatic Society of Bengal, is perhaps a disadvantage. If with the grant of a Royal Charter

adquarters is moved to Delhi, this should cause all such jealousies to be dispersed

In conclusion, it can be emphasized that Prof. Hill's report is a document of the greatest public value, which will provide a first-class stimulus to scientific progress in India. At present few copies are available in England, but it is to be hoped that this deficiency will be rectified later. It is of such importance that it should be studied closely by all who are interested in the welfare of India as conditioned by its scientific progress.

DRY FARMING PROBLEMS

Dry Farming in India

N. V. Kanitkar (Imperial Council of Agricultural Research, Scientific Monograph No. 15) Pp. x+352. Delhi: Manager of Publications, 1944. 13 12 paces, 21s 6d.

More than one fifth of India's total cultivable area crops have to be grown under conditions precarious and inadequate rainfall. The area concerned exceeds seventy-seven million acres. A partial crop failure is a serious matter for the sixty million people who live there, and for many others outside who receive their food-grains from the affected areas. The danger has become steadily greater because of the continuous and rapid increase in the total population, not only are there more to be fed, but also the increasing pressure on the land has reduced the average area cultivated by one family on the better lands, and has caused more marginal land to be taken into cultivation and has thus intensified many technical difficulties inherent in the system of subsistence farming.

During the past ten years, the Imperial Council of Agricultural Research has financed and co-ordinated the work of five special stations set up to examine the scientific and technological problems of dry farming, or crop-growing in low-rainfall areas. The scientific monograph under review is an account of the work. One of the stations, Rohtak, is situated in the north-east Punjab, on the alluvial Indo-Gangetic plain. The other four are in peninsular India and are relatively close together, but cover the two main soil formations. The Sholapur and Bijapur stations in Bombay province are on the Deccan trap, which weathers into the well-known black 'cotton' soils. The remaining two stations are at Hagari in Madras, and Rachur in Hyderabad State. They are on the red and black soils associated with ancient crystalline granite and gneiss.

The monograph contains one or two general chapters, describing the rainfall distribution over India, and the prevalent agricultural practices in dry farming in India and elsewhere, but the greater part deals with the properties of the soils and the behaviour of crops at the five stations. Extensive chemical and physical analyses of the soils were made, but except for easily predictable differences in field behaviour, associated mainly with depth of soil and the degree of heaviness, the results are shown not to have any fundamental bearing on the question whether crop yields can be stabilized or increased. This is to be expected, for the factor that overrides all others in importance is the amount and distribution of the rainfall in any season. The results of the manurial

experiments brings out that point. Farmyard and green manures were tried with conflicting results (except possibly on the eroded areas of the peninsular India stations). Thus, the heavier dressing of manure often produced a smaller yield of grain than was obtained with the lighter dressing or no manure at all. The reason was shown to be that the nutrients encourage a greater vegetative growth than the limited moisture supply could bring to maturity. The effect is well known to the cultivators, who say that manure 'dries up' the crops, and are reluctant to use dung as manure, quite apart from their need of it for fuel. The greatest importance, therefore, is attached to the problem of conserving the maximum amount of water in the soil. A great deal of laboratory and field work is discussed, varying from cultivation and run-off experiments to plant transpiration trials. The reduction of run-off water by suitably placed bunds is shown to be of prime importance, and simple methods are described suitable for the cultivators' use. The results of the tillage experiments fall into line with the knowledge now available of the physical factors concerned in the behaviour of soil moisture. Over a period of years deep ploughing is no better, and may be worse, than shallow ploughing, and repeated ploughing is found to be harmful on some soils and ineffective on others. On the other hand, repeated shallow cultivations in the monsoon period do conserve water for the use of the subsequent winter crop, partly through weed destruction and partly by the prevention of deep cracks through which water from the lower levels could escape as vapour.

Developmental studies of the important crop plants were done mainly on the millets that, as sorghum or jowar (*Andropogon sorghum*) and pearl millet or bajra (*Pennisetum typhodeum*), are predominant in these areas. Shallower seeding than the customary is recommended, because the production of the secondary and permanent root system is encouraged, a lower seeding-rate and wider spacing of the rows is also urged, because larger grain yields are obtained, and the wider spacing permits inter-cultivation up to an advanced stage of growth without injury. All this is counter to the usual practice of the cultivator, and it is no criticism of the experimental results to sound a note of caution. There may well be incidental advantages in the customary methods, to be disclosed by experiments covering a longer period of years and a wider variation of climatic conditions. For example, tillering is not desirable in dry farming conditions, and the tendency is discouraged by the close stand of plants given by a heavy seeding-rate. Indeed, an automatic selection of non-tillering types may well have been effected by the practice of close seeding, for it is pointed out in the monograph that the sorghum varieties grown in south India do not usually tiller. Plant-breeding work was outside the scope of the investigation, but promising strains evolved elsewhere were tested against local varieties, with no very significant results, except that early maturity was valuable. It must be recognized that the plant-breeding problems in food crops for dry-farming areas are of peculiar difficulty, not only because of the extreme variation in conditions from season to season, but also because the weight and quality of the stalks and leaves, which are the main fodder supply for the animals, are as important as the yield and quality of the grain.

Another point on which longer trials are needed is the relative value of rotations and the cultivators'

practice—by no means confined to India—of sowing mixed crops

The monograph concludes with an account of the combined agronomic and costings studies in which the yields and costs of the methods worked out in the experiments have been compared, on a farm scale, with the present standard practices of the cultivator. Although each item, such as bunding, inter-cultivation or manuring, gives no significant improvement, their aggregate effect over the seven years 1934–35 to 1940–41 is appreciable. The methods advocated for each of the main tracts are described in detail. The main agronomic and research problems on which further work is needed are also briefly set out. Most of them are clearly important, but the main conclusion gained from a study of the monograph is of the value that resides in the full farm trial (including costings) on a scale within the capacity of the cultivator, of the new methods against the old. It is to be hoped that this feature of the scheme will receive even more attention, for it brings the experimenter and the cultivator together on common ground.

B. A. KEEN

space to explaining why certain procedures have been adopted. It is not clear why, in the determination of manganese in steel and magnesium alloys, oxidation to permanganic acid is effected by means of ammonium persulphate and silver nitrate, while, for the same constituent in copper and aluminium alloys, potassium periodate is used as the oxidant, nor is it explained why yellow filters are necessary when using the mercury lamp for determining manganese instead of the green filters which are used with the tungsten lamp and which are specified for other determinations with the mercury lamp. With the 'direct' methods which are described, certain interferences arise, and the need to correct for these is not mentioned in the text.

The utility of the book would have been increased appreciably by an explanation of these and certain other items, some of which conflict with my own experience. However, the book contains much information which should be welcome to laboratory workers contemplating the institution of absorptiometric methods, and it should make a useful addition to the library of the metallurgical chemist.

H. C. DAVIS.

ABSORPTIOMETRIC METALLURGICAL ANALYSIS

Metallurgical Analysis by means of the Spekker Photo-electric Absorptiometer

By Dr F. W. Haywood and A. A. R. Wood
Pp. xii + 128 (London: Adam Hilger, Ltd., 1944)
18s. net

WITH the advent of the Hilger 'Spekker' absorptiometer and the pioneer work carried out by E. J. Vaughan in applying this instrument to metallurgical analysis, absorptiometric methods have become widely popular, and this book has been published in order to meet the demand that has arisen for a volume containing a collection of methods which have been devised specially for use with the instrument known as the 'Spekker'.

The first of the two sections into which the book is divided is devoted to a full description of the principles underlying absorptiometric analysis and to the construction and manipulation of the instrument. In the second part are collected twenty-six methods describing procedures for the determination of the commonly occurring constituents of commercial ferrous, aluminium, copper and magnesium-rich alloys. Composite schemes of analysis are included for each class of alloy, whereby several constituents may be determined on one initially weighed sample of alloy without the necessity for chemical separations. The operation of the methods is fully described, including details for the construction of the necessary calibration graphs.

The presence of certain anomalies tends to detract from an otherwise well-written text. Thus, the ordinates of the many specimen calibration graphs are described as "drum readings" whereas the graphs are derived from "drum differences". In no less than four instances, 'direct' methods not involving difference readings are illustrated by 'typical' calibration graphs obtained from drum differences, in spite of the fact that in two of the cases it is stated that "Difference methods are not applicable". Such lapses are apt to confuse rather than assist. It is, perhaps, unfortunate that the authors did not devote more

INTRODUCTION TO PHYSICS

College Physics

By Dr C. E. Mendenhall, Prof. A. S. Eve, Prof. D. Keys and Prof. R. M. Sutton. Pp. viii + 61.
(Boston, Mass.: D. C. Heath and Co., 1944)
4 dollars

AN introductory course in physics should aim at presenting the fundamentals rigorously without being excessively mathematical in outlook, and should also arouse enthusiasm for the subject and stimulate the student to pursue it further. In planning this text-book for first-year students in American universities the authors have clearly had these intentions in mind. Fifteen chapters are devoted to mechanics and general physics, eight to heat, thirteen to magnetism and electricity, thirteen to optics, and two to atomic physics. Modern ideas and applications are kept in view throughout the book.

The general treatment is sound, and the principles are very carefully expounded. The sections on wave motion, sound, physical optics, electron physics, and radio are good. In some places the text is necessarily condensed; for example, geometrical optics is rather briefly treated.

A few minor points suggest themselves for criticism. A simple magnifying glass is said to give "considerable chromatic aberration"; Newton's law of cooling is offered as a small-excess approximation to the fourth-power radiation law; 'thermal capacity' is used to mean thermal capacity of unit mass, as in Figs. 537 and 539 on thin-film interference and Newton's rings are inaccurately drawn.

There are more than 650 well-chosen problems with answers. The book is well illustrated and adequately indexed. Viewed in relation to the needs of British students, it should be useful for First M.C. candidates, and for biologists and others to whom more severely mathematical approach makes no appeal. Its fresh outlook and clear presentation should commend it also to those students of related sciences who wish to appreciate what physicists are trying to do and how they are setting about it.

G. R. NOAKES

American Men of Science

A Biographical Directory Edited by Jaques Cattell
seventh edition Pp. vii+2033 (Lancaster, Pa.
science Press, 1944) 14 dollars

THERE is no published record in Great Britain from which one can obtain the scientific record of a particular individual, apart from those included in "Who's Who". Attempts have been made to meet the need, but they have not persisted. North America is more fortunate. Since 1906 it has had "American Men of Science", now in its seventh edition. It is a bulky volume, in spite of the large page used, but the type is admirably clear, as should be the case in any reference book.

For those not familiar with this work, it can be described as an alphabetical list of scientific men (and women) of the United States and Canada. Under each name the following data are given: address, date and place of birth, academic distinctions with dates, posts occupied, again with dates, membership of scientific societies, with offices held, and chief scientific interests. By the ingenious use of abbreviations and italics, a surprising amount of information is provided. It is estimated that the present volume contains 34,000 names, as against 4,000 in the first edition. 250 names are marked with an asterisk as those of leaders in their particular subjects during the past five years; they are selected by popular vote.

No doubt such a compilation is expensive to produce and to keep under continuous revision, but its usefulness makes it well worth while. Is it too much to hope that the money will be forthcoming for a similar reference book of British men of science? Much of the necessary material is already in existence on the cards of the Central Register held by the Ministry of Labour and National Service.

Elementary Statistics

by Prof Hyman Levy and E. E. Preidel (Nelson's Aeroscience Manuals) Pp. vii+184 (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1944) 5s net

THIS volume, in the series of Nelson's Aeroscience Manuals, covers the elementary ideas of statistical theory, including distributions, means, measures of dispersion, correlation, elements of probability, least squares and the normal distribution. The mathematical requirements are not very advanced and are carefully explained, and there are numerous examples and exercises. The book should be useful in giving a general idea of the subject to those who do not wish to specialize in it.

Statistical nomenclature is always something of a problem, but there are two expressions used in this book which the authors might reconsider. They refer to the arbitrary origin chosen to simplify the calculation of a mean as a "fictitious average", whereas most writers use the more descriptive phrase "working mean", and later on extend their usage to a fictitious standard deviation for the root-mean-square. Secondly, the authors give the result that the probability of r events in n trials with probability p is $\binom{n}{r} p^r (1-p)^{n-r}$ and call it Bernoulli's theorem. The result was certainly given by James Bernoulli (though Pascal probably knew it), but what is now generally known as his theorem in probability is the much more advanced result at the end of the *Ars Conjectandi*, to the effect that the proportion of successes in repeated trials approaches p with as great probability as is desired. M. G. KENDALL

Introduction to Differential Equations

By S. L. Green Pp. iv+140 (London: University Tutorial Press, Ltd., 1945) 7s 6d

IT is quite refreshing to see a new book on differential equations, and this introduction to the subject has been planned with skill and developed with a clear appreciation of the difficulties which usually confront the student. There are eight interesting chapters covering ordinary and first-order equations, including Bernoulli's equation, with applications to plane curves. Then follows a thoroughly sound treatment of partial equations and operational methods, with illustrations from surfaces and curves in space. Next come Lagrange's linear equation and total equations in three variables. Finally, there is a well-written chapter on solutions in series, embracing the method of Frobenius, Bessel's equation of order zero, and Laplace's equation.

The book is intended for students reading for university degrees in the faculties of arts, science and engineering. The course is one of pure rigorous mathematics with very few practical applications of the kind required by science and engineering students, although in the very numerous exercises set for the student's practice, several are drawn from physical problems. Nevertheless, the author has produced a thoroughly good book which gives a clear insight into some of the fundamental principles of so vast a subject. Not only is the volume of value to the student who is under the expert guidance of a teacher, but also the clarity of the style renders the text very readable and understandable to an intelligent private student. As the specialists in this subject are now unfortunately few, the book should be useful also to teachers for, after all, differential equations are fundamental to all applied science and engineering.

The book can be confidently recommended to all to whom the study of the subject is indispensable.

The Theory of Measure in Arithmetical Semi-Groups

By Aurel Wintner Pp. v+56 (Baltimore, Md.: The Author, Johns Hopkins University, 1944.) 2 dollars

THIS monograph, the title of which is somewhat abstruse, deals in fact with certain aspects of prime number theory. Though self-contained in presentation, it is a continuation of the author's "Eratosthenian Averages" (Baltimore, 1943). A knowledge of analytical prime-number theory and of Tauberian theorems is assumed, and even readers possessing this knowledge will probably not find the book easy reading. The greater part of it is concerned with the properties of the set of all integers that are divisible only by the primes of a given sequence, and in particular the various senses in which the set may have a 'density'.

The attitude throughout is typical of one tendency in present-day mathematics: there is a detailed analysis of the logical relation between every proposition and (almost) every other, and of the 'depth' of each proposition. Much of this is interesting and instructive, but I cannot help thinking that the book would have been more readable if the author had been less thorough.

There is a mistake (not important for the sequel) on p. 32: if $L(x)$ is a monotonic function which tends to infinity with x , and if $L(x) = O(x^\epsilon)$ for every positive ϵ , it does not follow that $L(x) \sim L(\theta x)$ for every fixed positive θ . The author has been misled by a statement of Pringsheim. H. DAVENPORT

SCIENTIFIC RESEARCH IN INDIA

TOWARDS the end of 1943, Prof A V Hill, one of the secretaries of the Royal Society, was invited by the Government of India to visit that country and discuss the organization of scientific and industrial research as part of the Indian post-war reconstruction plan, and its co-ordination with corresponding activities in Britain. Advice was also sought on current research problems, with visits to universities and other research centres. Prof Hill was thus enabled to obtain a view of the position and progress of science and industry in India more comprehensive than has been vouchsafed to anyone since the examination of the industrial resources of the country carried out by the Indian Industrial Commission under the chairmanship of Sir Thomas Holland during the War of 1914-18.

That Prof Hill took full advantage of this opportunity is apparent from his report, which has recently been published in India*. From the preface it is seen that the author regards this document rather as a logbook than as a formal or complete report. The material of the original logbook has, however, been regrouped into appropriate sections. These are necessarily many in number, so that to give a brief account of this important public document it seems desirable to mention the substance of each section, omitting Section 1, the Introduction.

Section 2 Lack of Scientific Liaison, and Section 4 An Indian Scientific Office in London

In spite of the absence of scientific and technical liaison between India and Britain hitherto, Prof Hill finds that there is a complete lack of any spirit of isolationism on the part of Indian scientific, technical, and medical men, and a frank recognition of the advantages of co-operation. To assure a liaison in the future, he proposes the establishment in London of an Indian Scientific Office with specialists in agriculture, defence, engineering, industry and medicine. This would follow a recommendation of the British Commonwealth Science Committee set up by the Royal Society.

"That a suggestion be made to the Governments of the various English-speaking countries that they should consider the possibility of maintaining permanent scientific representation in London and possibly also in other capital cities of the English-speaking world."

The Royal Society is prepared to set up a special committee of its fellows for the purpose of advising the Indian Scientific Office, the India Office, or the Office of the High Commissioner for India, on any special matter desired, for example on the filling of important scientific posts in India when suitable men are not available in India.

Section 5 Scientific Liaison with the United States.

India has many problems in common with the United States, for example, dust, erosion, floods, rural health and nursing services, control of pests, irrigation and hydro-electric developments. The British Central Scientific Office established in Washington since 1941 acts now for the Dominions as well as for the United Kingdom, and the attachment of representative Indian men of science to this office would be welcomed both by the director thereof and by the Americans.

* Scientific Research in India. By Prof A V Hill. Pp 40 (Simla Government of India Press, 1944).

Section 3 Research Training of Young Indians in the United Kingdom

India has been largely cut off intellectually for nearly five years from the rest of the world, and it is urgently necessary to resume and enlarge arrangements that existed before the War for advanced study abroad, especially in Britain, by young Indian teachers, research workers, and members of technical staffs. On the other hand, the universities, medical schools, technical colleges, and research laboratories of Britain will be overwhelmed after the War with applications from others whose claims it will be difficult to resist. This means that there will be a severe competition for such facilities, and it will be imperative that the Indians sent overseas should be carefully selected. Such training will have to be financed by Government, but as Prof Hill points out, there should be no difficulty over this as the sterling balance of India in Great Britain is already about £1,000 millions.

Section 6 A Research Background in Medical Education

As a physiologist, Prof Hill was given special opportunities of seeing hospitals, medical colleges and departments of medical science. His general criticism of medical education in India is that there is little significant research done at the medical colleges either in (a) the pre-clinical sciences (anatomy, pharmacology, physiology, or normal psychology), or (b) pathology and bacteriology, or in (c) clinical science. The fundamental cause in each case is that departments are much understaffed, and of such staff as there is, most are only part-time employees of the colleges, depending usually on private practice for the major portion of their income. Prof Hill cites the report of the Goodenough Committee in Britain as to the staff necessary for the various departments of a university medical centre, but he realizes that nothing on the same scale can be done in India at present, except at one or two centres because there are not enough people of sufficiently high standard available. Also there would probably be considerable opposition to the full-time principle. Further, the universal adoption of provision for medical education on the scale suggested is bound to be very expensive.

Section 7 An All-India Medical Centre

Recognizing the importance to any country of a really high type of medical practitioner and of a high type of medical teacher and research worker, Prof Hill advocates the establishment of an All-India Medical Centre, staffed in all departments by the ablest people available anywhere, employed full-time and adequately paid. To attain this end, liberal expenditure on scholarships will be required. Further in order to avoid communal, political, inter-provincial and inter-State rivalries and jealousies, this Centre must be established at Delhi. It is desirable, if possible, that it should be built, equipped and endowed entirely from voluntary gifts, so as to strengthen its hand against eventual political or other pressure, and Prof Hill suggests that such an All-India Medical Centre might be a very fitting national memorial to the Indian Forces after the War.

As malaria in India is the most serious public menace, Prof Hill suggests that as part of this All-India Medical Centre there should be a special hospital for the clinical study of malaria.

Section 8 Medical Research

Although medical colleges in India generally lack the research atmosphere for reasons already given, yet India has a high reputation for medical research, specially into tropical diseases (for example, malaria, cholera, plague, and kala-azar). This work has been done in the main at special institutes, for which the research department of the Indian Medical Service has been mainly responsible, helped by grants and salaries provided by the Indian Research Fund Association. The latter is an independent registered body drawing its funds from a 'user' department of the Government of India (Education, Health, and Lands). It should rank with the Medical Research Council in Great Britain, but does not because of the inadequacy of its funds. Prof Hill would like these medical research institutes, where practicable, to be brought into closer contact with medical colleges and higher medical education, to the mutual benefit of both, this should also be borne in mind when new medical research units are planned.

Since the object of medical research is treatment of the sick and improvement of public health, it may help to give some idea of the magnitude of the medical and health problems before India if the reviewer intercalates here a comparison made for another purpose of the financial provision for medical and health purposes in India and Malaya respectively. In 1938 the provision in the Federated Malay States estimates under 'Medical and Health' was 2 43 dollars Rs 4-4-0 per head or 180 dollars per square mile. In India the expenditure on medical relief in twelve provinces varied in 1936 from one anna per head in the United Provinces to 8 annas 8 pies in Baluchistan. For Madras alone, from which the Tamil population of Malaya is largely derived, the figures were 2 annas pies per head and Rs 53 per square mile. Thus for Madras the provision per person was only one twenty-sixth of that in the Federated Malay States, while measured by area it was one sixth [Straits dollar = 2s. 4d. Rupee = 1s. 6d.]

Section 9. Vital Statistics and Population

Prof Hill directs attention to the rapid increase in the population of India and to the fact that improved public health and nutrition, and diminution of the present high mortality, will cause the population to increase at a still higher rate, at least for some time; so that, contrary to what is commonly thought, industrialization, with a resultant higher standard of living, may at first also cause a rise in the birth-rate. The decision regarding the direction in which the available effort for national development should be applied depends largely upon a public understanding of the facts and probable trends of morbidity, mortality, reproduction, and population, more accurate data on these points, and their more detailed analysis, are required.

Section 10. Agricultural Research.

Agriculture is India's most important industry, but great expansion is necessary, first to provide more adequate nutrition for the present population of some 300 millions, secondly to anticipate the needs of the expected increase of population, and thirdly to provide for the expansion of crops required for industry and export.

Excellent work is being done in India in agricultural research by a variety of organizations maintained both centrally and provincially and by Indian

States. Nevertheless, the total expenditure is only two thirds of that in Great Britain before the War on agricultural research, although Great Britain has only one eighth the population and one twentieth the area. The expenditure in India is still only about one quarter of an anna per person per annum, and one tenth of an anna per acre of the total area.

Section 11. Surveys and Natural Resources

The great natural resources of India are still inadequately known. Consequently the Geological Survey must be expanded, the Botanical Survey restored, and the Zoological Survey extended. The proposed research institutes on marine and freshwater fisheries should be set up as soon as possible. Other subjects, such as water-power, water-supply, forests and soil, require fuller investigation. A central research board for surveys and natural resources is recommended.

Section 12 Industrial Research under the Government

The Board of Scientific and Industrial Research founded in 1940 has already produced important results, but the headquarters staff assisting the Director of Scientific and Industrial Research is far too small. It will be important for this Board to be in close and familiar contact with the Department of Scientific and Industrial Research in Britain and with corresponding bodies in the Dominions.

Section 13 Scientific Research by Industry

Examples are given of the giant research organizations maintained in the United States and Britain by some of the leading industrial organizations, for example, the Bell Telephone Laboratories in New York, the Eastman Kodak at Rochester, N.Y., the G.E.C. at Wembley, Imperial Chemical Industries, Ltd., Burroughs Wellcome, Lever Bros., and various engine and aircraft firms. In addition to these many private enterprises of individual firms in Britain, there are twenty-four industrial research associations maintained jointly by industry and the Department of Scientific and Industrial Research.

In India the nearest approach to the American and British model is the Metallurgical Laboratory of the Tata Iron and Steel Co. Admitting that India as a whole is poor, and that the number of men capable of the requisite effort in any field is very limited, Prof Hill thinks that Indian industry is not yet making nearly the research effort it could on its own behalf, especially as some of its industries have recently been prospering exceedingly.

Section 14 Technology.

In Great Britain there is as yet no institution comparable in magnitude, in the quality of equipment and in excellence of teaching and research work with the Massachusetts Institute of Technology at Cambridge, Mass., the view is held in Britain that two or three such institutions should be set up, or that existing institutions should be expanded for the purpose, at such centres as Glasgow, Manchester, Birmingham and London. This being the view held in a country where, after all, the conditions are not so bad, how much more can we recognize the necessity for one or two such institutes or colleges of very high standard in India? For the future of Indian industrial and agricultural development must depend on the supply of first-class technical brains, trained in an atmosphere of original research and practical

experience Of existing organizations, the Indian Institute of Science at Bangalore comes closest to what is wanted One chief purpose of the proposed new institutes of technology would be to provide teachers and research workers of high quality for other places

Section 15 Meteorological Research

The requirements of the Fighting Services and particularly of the Air Force, and the needs of civil aviation, have expanded greatly the usefulness of the India Meteorological Department, but meteorology has many other applications, for example, in radio and, in India particularly, in agriculture and in emergency warning of floods Proposals have been made to the Board of Scientific and Industrial Research for the further development of fundamental research in meteorology in India, and these proposals have been accepted.

Section 16 Scientific Instruments and Equipment

This is a key industry, and urgently needs encouragement Given training and experience, Indian workmen have all the natural aptitudes for such manufacture (as has been demonstrated for many years by the Survey of India)

Section 17 Post-War Disposal of Government Stock

A considerable amount of scientific and medical equipment and machine tools will be available after the War Prof Hill recommends that a free distribution should be made to university and other institutions of the equipment they require, for one of the most obvious criticisms of the majority of university laboratories in India refers to the poverty of their scientific equipment and the frequent absence of any proper workshop facilities and tools

Section 18 Research for Fighting Services

The existing research organization of the Defence Services in India was not designed for the contingency of India being the base for major naval, military and air operations Any improvements that can now be made in the arrangements for research in connexion with the Services should be planned not only for the present War, but also in view of the future necessity of the Government of India under a new constitution taking full responsibility for her own defence Prof Hill proposes a War Research Board in liaison with a Central Organization for Scientific Research

Section 19 A Central Organization for Scientific Research

This is the most important section of Prof Hill's report, because it contains constructive proposals for remedying the various shortcomings in the provision for scientific, medical, and industrial research that his survey has brought to his notice Prof Hill first enumerates and describes the various co-ordinating research bodies set up in Britain, namely, the Medical Research Council (1914), the Department of Scientific and Industrial Research (1916), the Agricultural Research Council (1931) and the War Cabinet Scientific Advisory Committee (1940) He proposes for India a Central Organization for Scientific Research working under the Honorable Member for Planning and Development, to control and co-ordinate six research boards, namely, medical, agricultural, industrial, engineering and war, and a board of surveys and natural resources

Section 20 A Central Register of Scientific and Industrial Personnel

The Scientific Section of the Central Register in Britain has proved of much value in selecting scientific and technical personnel for work connected with the war effort It is regarded now as an institution of permanent value to the country, but how it will be organized and used in peace-time has not been decided Prof Hill considers that a similar register would be of use to India, and has suggested that the National Institute of Sciences of India should undertake its construction The Board of Scientific and Industrial Research has made a suitable grant to the National Institute for this purpose

Section 21 Pay and Status of Scientific Workers in Government Service

One of the defects of employment in Government service both in Britain and India is that the administrator is usually much more highly paid than the scientific or technical man of the same standing, experience, training and ability, so that the scientific man has been unable to attain more than a very limited position and salary without undertaking administrative work This difference requires modification if Government is to secure the ablest men in science and give them the best opportunities for developing and using their talents

Section 22 Scientific Societies in India

Prof Hill points out that scientific societies are of two kinds, general and special, and that both kinds have an important part to play in the publication of scientific papers and results as well as in the formation of libraries and collections "Scarcely less important is their influence in making living communities out of a number of people always critical and often highly individualist In India where so many causes tend to present to separate individuals, groups and communities from one another, a strong common interest in science as a whole, or in some branch of it, could have as a by-product an important influence in keeping people working sensibly together" Prof Hill outlines some of the ways in which these societies could be assisted and encouraged by Government without diminution of their independence Once the National Institute of Sciences of India has been formally recognized as fulfilling in India functions similar to those of the Royal Society in Britain, it will be available to take up various matters with Government on behalf of sister societies, and to distribute Government grants for certain scientific purposes, such as grants for publications, and grant-in-aid for scientific investigations and for international scientific conferences A beginning has been made by entrusting the National Institute with grants for publications and for the preparation of a Central Scientific Register

Section 23 Scientific Research in Indian Universities

This subject would require long and careful study and a small commission under a scientific man as chairman might well be appointed to study the whole subject Meanwhile, Prof Hill remarks that scientific research in the universities, both for its own sake and as a background for scientific education, is the fundamental basis of all scientific progress The most notable contributions of Indian men of science have been in physics, mathematics and chemistry, and there are in fact a good many strong departments:

physics and chemistry at Indian universities. But in the biological sciences and in geology, the departments, where they exist, are nearly always small, ill-equipped and under-staffed. Even allowing for the founding of a few colleges of technology, there will be a need for universities to maintain departments in engineering of a sufficient standard to meet the ordinary needs of industry and public works. Last year the Royal Society set up a number of special committees to investigate the post-war needs of fundamental research in the United Kingdom. Similar investigations would be valuable in India.

Section 24 Private Benefactions in Science.

Although substantial benefactions have been made to science, medicine and technology in India from private sources, particularly by the Tatas, yet most scientific work in India derives its financial support from the Government. There are in India many rich men who could easily contribute substantially to scientific research. What are specially needed are scholarships, which if endowed could commemorate the names of the donors, on the parallel of the numerous endowed scholarships, studentships, and fellowships in Britain and the United States. There are already in India a few completely non-official privately endowed scientific institutions, for example, the Indian Association for the Cultivation of Science and the Bose Institute in Calcutta, and the Tata Memorial (Cancer) Hospital in Bombay. Here is a great opportunity for Indian benefactors.

BIOLOGY TEACHING IN SCHOOLS AND UNIVERSITIES

ON March 24 the Association of British Zoologists met in the rooms of the Zoological Society of London, with Prof. James Ritchie in the chair. The morning session was devoted to a discussion of the interrelationship of biology teaching in schools and universities.

In opening the discussion, Dr C. F. A. Pantin directed attention to the ultimate objects of a biological training. The first duty of a university biological department is to advance knowledge. The depletion during the War of university staffs in zoology has shown how serious the situation could become when research ceases and when individuals with expert knowledge in special fields cease to be available. The training of able students for university posts is essential. Nevertheless, the numbers required each year are few, and the vast majority who receive biological training at a university aim at some other professional career such as teaching in schools.

Important as biology is in education, one would not wish to produce biological instructors simply for the sake of training yet more. In the past, preliminary training for medicine occupied the largest number of zoological students who aimed at other careers, though their contact with the subject was brief. Only a few zoologists were absorbed into other professions. But one hopes to see in the future a steady and increasing demand for careers in veterinary work, agricultural entomology, fisheries in Britain and in the Colonies, as well as in special activities such as the protection of stored products and the prevention of fouling of ships.

It is probable that more zoologists will be required for professional or Government services than for industry. The problems of applied biology are rarely narrow and local. They may cover the whole country and may lead into physics, chemistry, mathematics and even more distant studies like sociology. There is little scope for technicians with limited but intensive training comparable to that of the radio expert in physics. The social importance of biological problems is not less for that reason.

However, the War has shown the value in an unexpected direction of the wide training a biologist receives. It has been the common experience that biologists are peculiarly fitted for the varied problems which come under the heading 'operational research'. Their advantage seems to depend on the fact that they are more accustomed than the physicist to hunting for general principles in a mass of apparently unconnected particular instances. The biologist cannot afford to reject any problem just because he is unable to examine and control it at leisure in the laboratory. He must often start with varied, qualitative and above all fugitive data. His problems are often of a kind which a physicist would reject as unsatisfactory for attack. But it is the solution of just this kind of difficulty which is needed in everyday life. We may hope that after the War biological students may find their place, attacking the general problems of industry just as they have attacked those of operational research.

It is clear that the preparation of the young biologist for any career will require a wide and sound scientific training. How far does the present educational system provide this? The universities have often complained that the teaching at school is too specialized; an attempt is made to cover too much ground, so that elementary knowledge is weak and the necessary revision at the university bores the student. It is also claimed that another result of this specialization is lack of general education and inability of the student not merely to read languages other than his own but even to express himself in his mother tongue. Though this may be partly true, it is open to question whether the degree of illiteracy among biological students is as great as some have supposed. Another criticism directed at university entrants in biology is that their knowledge of mathematics and physical science is too weak. Many university teachers have been told "I took up biology because I was not good at physics".

In all these criticisms there is some substance. But from the point of view of the universities, perhaps the most serious criticism of all is that under the present system the standard of knowledge of entrants in biological subjects varies so greatly that the construction of satisfactory preliminary courses at the university becomes extremely difficult. Pessimists have said that the only solution is to begin biological training at the university. They quote the case of the classic who turned over to biology and outstripped the rest of the class. They usually omit to remark that this is only characteristic of men of outstanding ability who would succeed in whatever direction they turned. But, in fact, teaching of biology at schools has come to stay. It must never be forgotten that the majority of school-children are not in fact going on to a university at all, and the case for giving the general citizen an elementary biological training is overwhelming. Moreover, a good school training in biology can be of the very greatest value to the university entrant. Time

presses, and education is long and expensive. It may be further encroached upon by national service. Everything that helps the student on his way without detriment to educational principle is to the good.

Those who are responsible for teaching in schools fully agree that the relation between natural science at school and at the university is very far from satisfactory. They point out, however, with justification that they are the victims of circumstances. They complain of the very high standard demanded in scholarship examinations, particularly those of the colleges at Oxford and Cambridge. It was realization of the force of this complaint which led to recent conferences between school teachers and college and university officers at Cambridge. As a result of these conferences, the principle was accepted that the factual basis of the scholarship examinations should be the same as that for the higher school certificate examinations in natural sciences subjects. But while this should ease the situation, nothing can really justify the use of an examination designed to select the very few ablest university candidates as the basis of natural science education for every kind of child at school.

University scholarships are not alone responsible for the school masters' difficulties. The discussion showed how the laudable effort to reduce the long and expensive period of professional training, particularly for medicine, has resulted in specialized work being pushed into preliminary examinations. In England, preliminary medical examinations are commonly taken at school, and this has led to great specialization—a difficulty avoided in Scotland, where the examination remains a university one. Yet another difficulty faces the schools in that there are no fewer than eight separate bodies controlling certificate examinations, each with its own syllabus and each giving the successful candidate special 'credits' which are of university rather than school importance. It thus comes about that a biology master at school may have to break up quite a small class into three or four groups each pursuing a different syllabus. Further, these syllabuses are not constructed primarily because of their educational value at the school-level but are determined by university and professional requirements.

What can be done about this? The discussion showed the unanimity of opinion in favour of biological training at school being based upon the educational needs of the school-child. The needs of the majority of students who will not in fact go to a university are paramount, and these students require a general biological education. This would in fact also be desirable for the few who are going on to a university. In either case, specialized study anticipating later professional requirements is undesirable. Thus, many schools have complained of the demands made by embryology in the preliminary medical examinations. A thorough grounding in embryology is justifiable for the student of medicine at some stage, but detailed embryology is beyond the average school-child, and attempts to cover it make far too large demands upon teaching time.

It was pointed out in discussion that though special educational requirements should be discarded in favour of general biological syllabuses for schools, there is great advantage in some part of the syllabus being studied intensively. As remarked in the syllabuses recently published by the Cambridge Joint Advisory Committee for Biology, one cannot train

scientific judgment when knowledge in all parts of the subject is scanty. But the part selected for intensive study should be one suited to the boy or girl at school, as is, for example, natural history. Further to ease the burden on the school-master and also to help preliminary work at universities, it is desirable that the school biological syllabuses of different examining bodies should have common aims and cover approximately the same kind of ground. Finally, in the interests of wider education, the total time spent at school on biology and indeed on natural science should not encroach too far on other fields of education. More than one recent conference between school-masters and university teachers have recommended that natural sciences subjects should not occupy more than two thirds of the teaching time.

It was with these things in mind that the Cambridge Local Examinations Syndicate and the Cambridge Syndicate of the Oxford and Cambridge Schools Examination Board recently set up a Joint Advisory Committee with members of the school-teaching profession to examine and report on their higher certificate syllabuses in natural sciences. These reports have now been published, and have in general had a very favourable reception. This Committee has tried to base its syllabuses on the various natural interests of the child. In zoology it has taken these to be the structure and function of the human body, the variety of form and function in the animal kingdom, natural history, the relation of animals to man and other topics. Embryology is much reduced compared with current syllabuses. On the other hand, great stress is laid on the importance of natural history, because of the training it gives in observation and in the acquisition of knowledge at first hand, as opposed to the passive absorption of selected ideas in class. The syllabus indicates how the science of zoology can be built up from this basis. Thus the study of man is a starting point, rather than an anthropocentric goal. Scientifically this is good, because many questions of structure and function first arise in the study of one's own body and can most easily be examined in it.

One other question of considerable importance was discussed. Is it better that a young biologist at school should study zoology and botany as separate subjects or make one common study of biology? Certainly at an elementary stage there are no good grounds for any separation. From an educational point of view the single subject of biology has every advantage. But the encouragement of biology rather than zoology and botany separately, raises certain difficulties in examinations. The school biologist is better trained who takes, say, biology, chemistry and physics rather than zoology, botany and some other subject. Yet the biologically minded student who takes the first combination stands at a disadvantage, since he has only one subject and not two in which he is likely to score credit. His situation is even more unsatisfactory when compared with that of the boy or girl taking physical sciences, who can choose three subjects, mathematics, physics and chemistry, for all of which he is mentally apt. This difficulty must in some way be overcome. It is part of a general problem which faces the educational system of Britain at the present time. How can we encourage a student to take subjects in which he does not excel, but which will be of the utmost value to him educationally, or even for the prosecution of his favourite study at a more advanced stage?

OBITUARIES

Mr A. R. Hinks, C.B.E., F.R.S

THE death, on April 14, at the age of seventy-two, of Mr Arthur Hinks, for thirty years the distinguished secretary of the Royal Geographical Society, leaves a gap which it will be difficult to fill.

A mathematician and a graduate of Trinity College, Cambridge, Hinks devoted his attention to astronomy during the earlier part of his career, and it was for his work bearing upon the determination of stellar and solar parallax that he was awarded the gold medal of the Royal Astronomical Society in 1912, and was elected a fellow of the Royal Society in the following year. In accordance with a tradition observed by Sir Isaac Newton, but reaching back to the Greeks, geography is merely a branch of astronomy, and Mr Hinks's interest in the earth as a planet, expressing itself in a series of lectures, and later of admirable text-books, upon surveying, cartography and map projections, led to his connexion with the Royal Geographical Society. His appointment as assistant secretary, and two years later (in 1915) as secretary, in succession to Sir John Keltie, was particularly apposite, since the fellows and Council of that Society were still primarily interested in travel and exploration, and Mr Hinks not only organized and supervised the *ad hoc* instruction of intending travellers in practical surveying, but also was able to assist them in the interpretation, working up and presentation of their observations on their return. The most recent edition of the well-known "Hints to Travellers" is largely from his pen, and represents the fruits of his numberless contacts with British and foreign explorers. During the War of 1914-18, he was also able to be of very great assistance to the military in solving or advising upon various technical problems connected with maps, and it was for his services in this direction that he was made a C.B.E.

Mr Hinks's own preoccupation with mathematical geography, and the Society's traditional function as a headquarters for exploration, had the result that the university geographer, attempting the systematic regional study of the earth and the interpretation of landscape, received rather a cold welcome at the House in Kensington Gore. The secretary was also editor of the Society's *Journal*, and his criticism and rejection, as editor, of academic research was by many felt to be unsympathetic and unduly harsh; but actually his standard of scholarship was high, while the achievements of British geography have been decidedly mediocre. The reason is not far to seek. There is an almost complete absence of scholarships, fellowships, research endowments and other opportunities for advancement and reward in geography, which naturally deters young men and women of first-class calibre from reading the subject at the universities. It was peculiarly unfortunate, in view of the help he might have given, that Mr Hinks accepted the Royal Society's view that geography is not a part of natural knowledge, and does not fall under the head of "the examination and investigation of experiments and of natural things" for which under the Charter of 1663 that Society could lawfully hold meetings. Hence, except in its mathematical aspects, the subject of geography lacks status and can command no financial assistance.

Within his chosen field, Mr Hinks himself contributed many valuable papers to the *Geographical*

Journal, the subjects including photogrammetric survey, boundary delimitation, geodetic problems, cartographic technique, and novel or neglected projections. Quite recently, he designed and calculated a series of maps on the oblique Mercator network, accompanying them by a family of curves by means of which great circles could be plotted between any two points. The maps were immediately used in a discussion of the future of civil aviation. He was responsible, too, for the design and calculation of the very beautiful and effective map of Europe and the Middle East which was drawn by the Society's draughtsmen and published for the British Council. For beauty and elegance in map production, in so far as it was an expression of perfect fitness for function, he was always deeply concerned, and took part in many lively discussions upon alphabets and lettering with the officers of the Ordnance Survey.

Mr Hinks's eminence in the fields of geodesy and cartography received world-wide recognition, and he was the recipient of the Royal Geographical Society's Victoria Medal in 1938, followed by the American Geographical Society's Cullum Medal in 1942. The present War robbed him of those years of leisure in retirement which were his due. He remained at his post, and only a few days before his death was answering correspondence upon projections, revising his standard text-book on the same subject, and giving vigorous expression to his opinion of a poorly conceived, badly designed and wretchedly executed map issued by a great public corporation.

E. G. R. TAYLOR

Mr. G. V. Boys

GEOFFREY VERNON BOYS, secretary of the Institution of Naval Architects, died on March 15 at St Mary Bourne, Andover. He was the only son of the late Sir Charles Vernon Boys, whose death at the age of eighty-nine occurred a year ago, and was born in 1893 at Oxford, where his father was then repeating, with improved accuracy, the Cavendish experiment, when he obtained 5.57 for the mean density of the earth.

G. V. Boys was educated at Marlborough and proceeded to Trinity College, Cambridge, in 1913. At the outbreak of the War in 1914 he served in the Royal Engineers, but was taken prisoner in August 1914. After spending some time in German prison camps, he was interned in Switzerland and resumed his residence at Cambridge in 1919, graduating in 1921. In the year following he lectured at the Royal College of Science, South Kensington, and in January 1922 joined the staff of Messrs. Kennedy and Donkin. As a senior engineer in this firm, he showed great skill in the use and application of mathematics and physics to engineering, and was frequently given difficult problems in design and always solved them. His work had the great merit of being accurate, and he possessed the admirable quality, especially in the application of science to engineering, of judging correctly the accuracy required without wasting time on irrelevant places of decimals. He was engaged *inter alia* on the Uhl River hydro-electric scheme for the Punjab Public Works Department and on many electricity transmission schemes, such as those in the Isle of Man and in Northern Ireland. He was responsible for the design and testing of the Central Electricity Board's grid towers in Scotland and north-west and south-

west England, which are used to transmit electricity at 132 kilovolts throughout that part of the country. The work which he carried out for Kennedy and Donkin was of great value to them and was much appreciated on account of his sound judgment and his facility in finding the best method of attacking any complex problem.

In 1935 Boys was appointed secretary of the Institution of Naval Architects. He filled this post with great success and was popular with the members and staff and trusted by successive presidents of the Institution—the late Viscount Stonehaven and Admiral of the Fleet Lord Chatfield. Boys was also a good linguist, and when the Institution was invited to Germany in 1939, he attended as one of its representatives. He quickly became convinced of Germany's warlike intentions and on his return volunteered his services to the Admiralty. His offer was accepted, and in September 1939 he moved to Bath and became professional secretary to the Director of Naval Construction, retaining general control over Institution affairs. Although he was not a naval architect by training, he was soon giving useful help to the directors under whom he served—Sir Stanley Goodall and Mr C S Lillierap. Ill-health forced him to retire from the Admiralty in 1944. During his fatal illness he wrote or dictated letters to the office and his friends so long as he was able and showed great courage and patience throughout.

Boys had a good personality, mixing well with those he met, and was a man of knowledge and ability in many directions. He leaves a widow and a young son.

L WOOLLARD

Mr. F. Percy Smith

F. PERCY SMITH, one of the pioneers of British film production, died on March 24.

It was in 1908 that Smith threw up an appointment with the Board of Education and gave himself up entirely to cinematography. He started working for Charles Urban and specialized in Nature and microscopic work. Even in these early days he had developed his special technique of speeded-up cinematography and had shown, in "The World before your Eyes" series, the beauties of the flower unfolding on the screen. Smith worked for Charles Urban for several years, but had no real opportunity of showing what he could do until in 1921 he joined Bruce Woole and took his part in the production of the "Secrets of Nature" series which, largely through Smith's contribution, has gone on ever since and has thus created a record for this or any other country of continuous production over a period of twenty-five years.

British cinematography has suffered a great loss as Smith's work was known and admired in nearly every country where cinematograph films are shown. Whenever a representative selection of British films has been shown to special audiences, something emanating from Smith's studio has always been included. In 1930 at the gala presentation organized by the Federation of British Industries to the delegates to the Imperial Conference his "Plants of the Underworld" was shown, and later, in 1933 at a similar gala presentation to world press representatives, he contributed "Gathering Moss".

Although much of Smith's work was shown in the theatres, and many will remember the weird beauty of his "Plants of the Underworld" and the drama of "The Life of a Plant", yet his main work was

rather in the scientific film. Here he was undoubtedly in a class by himself, especially in the field of biology. In collaboration with Dr Julian Huxley, he contributed a series of biological subjects that have done more to bring about the use of the cinema film in schools than any other single event. In connexion with this, Dr Julian Huxley remarks "Percy Smith had extraordinary patience and pertinacity in getting the results he wanted. In addition he was extremely ingenious in devising apparatus and gadgets of every description. His work was essential for the building up of high technical standards in the difficult art of biological film-making."

Although his studies of the chick and the frog were of very high quality, there is little doubt that it was his botanical films made in collaboration with Dr E J Salisbury that opened up fresh possibilities to the cinematograph camera. As Dr Salisbury writes "Mr Percy Smith was a first-rate cinematographer, who combined great technical skill with patience and observational acumen. The film which he took of the growth of roots is not only one of his most successful efforts, but exemplifies these qualities in a high degree. The knowledge of what is the life-history of a plant or its normal behaviour under particular conditions is not the end, but only the starting point in their pictorial portrayal. It was in the patience necessary to ascertain the precise phase of a phenomenon that best lent itself to pictorial record that Percy Smith exhibited so high a degree of skill almost amounting to genius."

The study, research and the patience that were necessary to complete such subjects as the life-histories of the fern and the moss were enormous, and nobody except a person whose sole interest lay in his work would have undertaken them. The fern film took three years to complete and that on the moss two and a half.

In the field of international competition, Smith's work had upheld the prestige of Great Britain, and prizes had been awarded his films in open competition against all comers, notably at Brussels and Venice.

Smith's was a strange personality. He had no thought for anything other than his work, and the only assistant he would tolerate was his wife. He was of a retiring and shy disposition, but with a keen sense of humour and a positive genius for the invention of 'gadgets'. In his studio he had machines to record the growth of plants, these, of course, had to work night and day. They were controlled by clockwork, made by himself, and it was essential they continued to function continuously, sometimes, for several weeks. As even he must sleep sometimes, he devised a means whereby if any of the machines stopped for any reason, it rang a bell by his bedside and woke him up.

In Percy Smith the British film industry loses a lovable personality and one whose work has done more than a little to uphold the prestige of British films. The sympathy of all will go out to his wife, who assisted him so ably, in her great loss.

WE regret to announce the following deaths

Miss Emilia F Miram, of the Zoological Museum of the Academy of Sciences of the U S S R

Prof Andreas P Semenov-Tian-Shansky, honorary president of the Russian Entomological Society

NEWS and VIEWS

Chemical Society: Retirement of Mr. S. E. Carr

FIRST as assistant and, later, general secretary, Mr Stanley Ernest Carr has been identified with the Chemical Society for forty-two years. Mr Carr's life's work has been such that much of the Society's progress must be ascribed to his guiding influence during that long period. Of necessity, there have been frequent changes of honorary officers of a learned society, and it has to be left to the more permanent general secretary to preserve the continuity without which schemes for the advancement of the society and the science it represents would frequently fail or, at best, be only partly successful. The Chemical Society has been particularly fortunate in having Mr Carr as general secretary for so long and during two periods of difficulty arising from emergencies when the importance of chemistry to the nation has had to be recognized. The history of the Chemical Society since the beginning of the present century is, indeed, almost an account of Mr Carr's successful work for the Society and British chemistry. For example, on behalf of the Chemical Society, he has been intimately concerned with the introduction of the publication of the "Annual Reports on the Progress of Chemistry" (1904), the setting up of the Bureau of Chemical Abstracts (now, the Bureau of Chemical and Physiological Abstracts) and the setting up of the Chemical Council, so achieving co-operation with other societies and organizations concerned with chemical interests in Britain. Fellows of the Chemical Society owe a great debt to Mr Carr both for his efficient work for the Society and for his courtesy and kindness at all times. They will wish him a successful retirement in which he will have happiness in the knowledge of the gratitude of those with whom he has worked.

Royal Geographical Society Awards

THE King has approved the award of the Patron's Medal of the Royal Geographical Society to Sir Alfred J Mackinder, for his eminent contributions to geography, including the first ascent of Mount Kenya in 1899, and his long and distinguished service to the advancement of the science. His Majesty has given permission to the Council to postpone a recommendation for the Founder's Medal for 1945. The Council has resolved that the grant of the Society's awards for 1945 be postponed.

Lingualism in Indian Education

In the *Journal of Education and Psychology* (London, 1, No 2, July 1943), A I Patel discusses lingualism and Indian education. He surveys the results of the use of English as the medium of instruction in the earlier stages of education before the mother tongue has become an adequate mode of expression. He concludes that bilingualism hinders the process of education, renders its victims emotionally unstable, prevents moral development, dries up the sources of creative ability, and makes misfits of the students, adjusted to neither cultural group. The remedy is to realize that at present Indian education is neither Indian nor education. English should not be taught in the primary stage, but postponed to a late period in the secondary stage. It could rank as a second language, leaving the vernacular to be the medium of education. The present system, centred round the teaching of

English, has had a fair trial and has failed. The writer admits that there will be difficulties but that for the sake of India they ought to be faced and overcome. He recommends the use of Basic English, when the time comes to learn English. He does not want to exclude English because it is the one language which can provide vital contact with European culture and civilization, but Indian language and literature should be the basis of education.

Science-Teaching in Schools

YET another body speaks on the teaching of science in the schools of the future. The Essex Science Teachers' Association is an active one, holding several meetings each year under the able guidance of its secretary at the Mid-Essex Technical College, Chelmsford. It works for the advancement of science-teaching in all types of schools. The interim report, a fourteen-page brochure containing aims of science-teaching, suggestions for content of science syllabus and facilities for the teaching of science, is intended to be followed up with a series of publications dealing with science for the eleven-to-thirteen age-group, laboratory accommodation, etc. (The Content of the Science Curriculum in Post-Primary Schools. Interim Report of a Sub-Committee of the Essex Science Teachers' Association. Pp 11+14. Chelmsford Mid-Essex Technical College, 1944. 6d.)

The aims are admirably stated, a concise expression being given as "aims . . . to encourage pupils to learn the facts, principles and skills of science, to appreciate the spirit and service of science, and to acquire rational methods of working, observation, thought and expression." Material for the content of the syllabus, its order and depth of treatment, local environment, time requirements, scope and practical applications are all discussed. Rational suggestions are made with regard to sizes of classes, rooms and laboratories, equipment, workshop and repair facilities, staffing. Particularly valuable is the contribution of the non-science headmaster that concludes this much too brief report, many of the contents of which needed stating long and loudly, it is to be hoped that further publications will amplify many of the sections on facilities and content of syllabus.

Sixth Form Mathematics

THE Cambridge Joint Advisory Committee for Mathematics, set up in November 1943, consists of eight school teachers and eight representatives of the University of Cambridge. The Committee has published a pamphlet "Syllabuses for Examinations taken by Sixth Form Pupils" (Cambridge University Press, 1945. 6d.), containing a scheme of two years' work for higher school certificates and also for college entrance scholarships. It is recommended that the entrance scholarship papers should follow closely those for higher school certificates, and not give too much weight to advanced work. Pure and applied mathematics are regarded as a single subject, to which, even for specialists, not more than half the total teaching periods should be devoted. Another main subject, for example, physics, should also be taken, and at least one third of the total time should be reserved for general subjects. Having regard to the different requirements and levels of ability of the pupils, the Committee provides four different syllabuses, 'Subsidiary', 'Ordinary', 'Further', and 'Higher'. The 'Subsidiary' would be sufficient for

those taking mathematics as an auxiliary to economics or biology, and includes, as an option, statistical method. This is an innovation of the greatest importance. The 'Ordinary' is roughly the present higher school certificate course for a 'Principal' subject, but again statistics may be taken if desired. The 'Further' and 'Higher' are suitable for candidates for university scholarships. Astronomy may be taken instead of some of the more advanced mechanics in the 'Further' course.

The Committee recognizes the great diversity of the needs to be catered for, and has tried to make the syllabuses as flexible as possible. Criticism and comment will be welcomed, and a revised edition of the syllabuses will, if necessary, be issued in the light of experience and of suggestions received. It is hoped that the Oxford and Cambridge Joint Board, the Cambridge Local Examinations Syndicate, and the Cambridge colleges will accept the syllabuses as a basis for their examinations. Approval has already been expressed by the Institute of Actuaries, and it is hoped that other professional bodies and the Services will also find them suitable.

National Museum of Wales

AN important aspect of the annual report for 1943-44 of the National Museum of Wales is the evidence it provides of a council fully conscious of the Museum's educational function, which even under war-time conditions has been considerably developed. Lectures, demonstrations, special exhibitions, loans to research workers and schools, and the provision of facilities, material and instruction for teachers and students engaged in specialized work are striking examples of the valuable work being carried out by all departments. For the future, the opportunities provided by Section 100 of the 1944 Education Act for closer co-operation between schools and museums have been recognized. Accordingly the Council, in collaboration with the Welsh Department of the Ministry of Education, has already given consideration to the matter in relation to Welsh schools. Other authorities responsible for the conduct of museum affairs in a post-war world would do well to note this action. The Council also reports that its Memorandum on Museum and Art Gallery Services in Wales and Monmouthshire (summarized in the 1942-43 Report) has been forwarded to the Minister without Portfolio by the Welsh Reconstruction Advisory Council. With it the latter has sent a communication asking the Minister to give special attention to the importance of extensions to the National Museum being recognized as part of the official schedule of post-war reconstruction work; the provision of Government funds for an open-air museum as an essential auxiliary to the National Museum, and the establishment of a museum grant committee, there being a particular need for a grant for technical assistance to local museums in Wales.

Among the many other activities reported by the Council the following are noteworthy. Department of Botany: continuation of research on atmospheric pollen (see *New Phyt.*, 43, 49, 1944, and *Museums J.*, 44, 146, Dec. 1944). Department of Zoology: completion of a detailed list of all the mammalian remains of historic interest, and the continuation of the bibliographical indexing of Welsh species. Department of Archaeology: continuation of survey work on ancient buildings in Monmouthshire, and the preparation of a report on the antiquities of West Gower (at the request of the Ancient Monu-

ments Department of the Office of Works). Department of Geology: the provision (in response to many inquiries on various aspects of geology) of information relative to raw materials, water supply, drainage and roads. The Museum has made many interesting and valuable acquisitions during the year, and it should be noted that the important collection of Celtic antiquities found in 1943 in a bog near Holyhead, Anglesey, is now in the custody of the Archaeological Department. A full bibliography of the publications of the National Museum of Wales is a useful appendix to this report.

Museums and Post-War Educational Development

THE annual report of the Manchester Museum (University of Manchester), while stating that the usual museum activities have been carried on during the year 1943-44, points out that its functions in relation to future educational developments can only be properly fulfilled when provision is made for a increase of technical staff, and for adequate working accommodation. As the report states, these needs are common to museums throughout Great Britain. At the present time, however, there are few or no signs that such needs—together with many others—will be met in the near future. No doubt the solution of the problem might be hastened if the Ministry of Education were to recognize in a more practical manner the considerable educational potentialities of these institutions. In the meantime, for lack of growing space, a valuable public service is unable to progress beyond its 'germination' stage.

Temperature Control

THE lecture on 'The Practical Side of Fine Temperature Control' delivered by L. T. Townson at R. Barrington Brock to the Society of Chemical Industry in May of last year is now available in pamphlet form as No. 11 of the review *Service Science* issued gratis by Messrs. Townson and Mercer Ltd., of 390, Sydenham Road, Croydon. The lecture dealt with constant-temperature baths, particularly for medium temperatures, and concentrated attention mainly on water baths, which the authors point out are superior to air baths both because of the low heat capacity of air and also, they say, because low density gives it little inertia, and enables vortices with consequent temperature differences, to form more easily. The first matter which the authors stress, and on which they give experimental evidence, is the importance of stirring. They believe that paddle stirrers are not sufficiently effective, and that the whole of the liquid must be caused to flow through the bath, this involves the use of a second chamber of some sort, either entirely separate, or formed within the bath by means of false sides or some similar device. Other points which are discussed in the lecture are the effect of thermostat lag, the advantages and disadvantages of proportional control, and the effect of heat losses. It is apparently realized that these lead to permanent differences of temperature in the bath. In this connection lagging is discussed, and the advantages of reflecting metal sheets as insulation are pointed out.

Biological Unit for Vitamin A

VITAMIN A is unique in that the unit by which it has been defined has been measured with reference to a precursor, β -carotene, and not to vitamin itself. This biological unit based on β -carotene standard is cumbersome and subject to gross errors.

Certain foodstuffs are now required by law to include vitamin A, and regulations require that foodstuffs, claiming to contain vitamins, be labelled in units. Manufacturers who to-day handle vitamin A are dependent on the spectroscopic method of assay using the extinction coefficient at 325–328 m μ as a linear function of vitamin A activity, and it has been necessary to adopt a factor to relate the spectroscopic reading with the biological international unit. Such factors have become standardized in Great Britain and in America although at different levels.

N T Gridgeman, in "The Estimation of Vitamin A" (Lever Brothers and Unilever, Ltd., 74, 1944), assembles and reviews the evidence. He shows that these factors do not rest on a sound scientific basis, due mainly to the occurrence of a number of vitamin A congeners and to the fact that the biological test is very complex, for example, there is the synergism of vitamins A and E. He recommends the adoption of a new unit based on the spectroscopic assay method. A provisional skeleton definition would be the unit of vitamin A is that quantity which made up to 100 ml with a specified organic solvent gives a solution having an extinction coefficient at 325 m μ of 0.005. He adds that "the quest for a new easily measurable physiological criterion of response, sharply related to increasing dosage, prophylactic or therapeutic, of vitamin A, can be regarded as a fruitful research problem".

Stars of the Southern Skies

LEAFLET No 188 (Oct. 1944) of the Astronomical Society of the Pacific, by Leon E Salanave, gives a simplified star chart and guide to observations with the unaided eye and with field-glasses. It has been compiled in response to numerous requests, from the South Pacific in particular, for star finders, constellation guides, etc., and is specially designed for a latitude 10° south of the equator. Only those stars are shown which are necessary to suggest the constellation figures, and after learning these the observer's knowledge can be extended with the aid of more complete charts. There is a brief description of the constellations, stars of the first magnitude, and of a few interesting objects such as the Great Nebula in Orion, the Large Magellanic Cloud, etc. The Leaflet will serve a useful purpose for those engaged in military operations who have found themselves under unfamiliar skies.

Association of British Zoologists

THE Association of British Zoologists, which had not met since January 1939 owing to the War, held its tenth annual general meeting on March 24 in the rooms of the Zoological Society of London. Proceedings opened with a business meeting during the course of which the following elections were made or, having been made by the Council, were confirmed: *President*, Prof James Ritchie, *Hon Secretary*, Dr John Smart, British Museum (Natural History), London, SW 7, *New Members of Council*, Prof.

L Mackinnon, Prof James Gray, Mr J C F. Fryer, Prof C. H. O'Donoghue and Wing-Commander F S Russell, *New Trustees*, Mr J. T. Saunders and Dr W E Swinton. After the business meeting, the Association proceeded to a discussion of the "Post-War Teaching of Zoology in Schools and Universities". This discussion was opened by C F. A. Pantin and is reported elsewhere in this issue (see p 535). In the afternoon, a series of four shorter discussions centring around the general topic of "Some Developments of Post-War Research"

was engaged in. The first, on "Marine Investigations", was opened by Dr E S Russell and this was followed by one on "The Work of the Zoological Society" opened by Dr S A Neave. Mr J C F. Fryer opened the next, on "Zoological Interests of the Agricultural Research Council", and the final topic was "Freshwater Investigations", opened by Dr E B. Worthington.

Frank B. Jewett Research Fellowships

FIVE Frank B Jewett Fellowships for research in the physical sciences have been awarded by the American Telephone and Telegraph Co to Dr Elliot R Alexander, Dr Albert S Eisenstein, Dr Kenneth Greisen, Dr Boris Leaf and Dr Harry Pollard. The availability of these men to accept their fellowships will depend upon the progress of the War, as each is now engaged in essential war research. Dr Alexander is at present a research chemist at the du Pont Experimental Station at Wilmington, Dr Eisenstein is a member of the Radiation Laboratory staff at Cambridge, Mass., Dr Greisen is engaged in war work at Santa Fé, New Mexico, Dr Leaf is an associate chemist in the Metallurgical Laboratory of the University of Chicago, and Dr Pollard is a member of the Applied Mathematics Group at Columbia University.

Announcements

THE following appointments have recently been made in the Colonial Services: D Sturdy, senior agricultural officer, Tanganyika, to be director of agriculture, Jamaica; E T. Ward, agricultural superintendent, Windward Islands, to be agricultural officer, Tanganyika; R K Hardy, assistant government chemist, Nigeria, to be government chemist, Nigeria; D R Rosevear, senior assistant conservator of forests, Nigeria, to be conservator of forests, Nigeria.

THE following appointments have been made to the technical staff of Ashe Laboratories, Ltd, 120/2, Victoria Street, London, SW 1. Mr D I Duveen now takes charge of the development of full-scale production of amino-acids and protein digests; he has worked in Paris and in London and has published papers, some in collaboration with Dr J Kenyon, on problems connected with optical activity and the preparation and isolation of substituted naphthalenes and their photo-oxides. Mr Duveen will be assisted by Mr E G Hatten, formerly of Glaxo Laboratories, who has had experience in the production of fine chemicals and therapeutic preparations. Mr H S Young, formerly with Messrs Crosse and Blackwell and C and E Morton, Ltd, has been appointed food chemist and will be responsible for the control and development of food preparations manufactured by the Ashe Laboratories. Mr P Lewis Smith, formerly with Messrs Eli Lilly and Co, has been appointed to the pharmaceutical section, where his long experience in the Far East will be of great assistance in the company's export programme. The new appointments will be under the general direction of Dr W E Gaunt, who is known for his work on amino-acids and protein digests.

ERRATUM—The new insecticide described in the communication entitled "Acaricidal Property of a New Insecticide, Hexachlorobenzene" printed in *Nature* of March 31, p 393, was wrongly named. The substance referred to is benzene-hexachloride, or 1.2.3.4.5.6 hexachlorocyclohexane.

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A New Rhesus Antibody

AN antibody of a type hitherto undescribed, which discriminates between certain Rhesus genotypes, has been found in the serum of a male patient, H.Br., of blood group O, suffering from a hæmolytic anaemia of uncertain aetiology. He was transfused on numerous occasions with unselected group O blood and ultimately began to have reactions suggestive of incompatibility. His serum was found to contain an agglutinin which clumped the red cells of all, but about 4 per cent of group O donors. The cells of one group O Rhesus-negative subject, C.K., were agglutinated down to a dilution of 1 in 640 by serum obtained in April 1944. In May 1944 the titre against cells of the same subject had fallen to 80 and in January 1945 to 20. Most of the investigation was carried out with the May serum.

The red cells of 662 group O donors and other subjects, unselected with respect to the Rhesus factor, have been tested with the serum. Twenty-seven, or 4.1 per cent, are unagglutinated or 'Br-negative'. Sixty-nine group O *Rh*-negatives, partly included in the above 662 subjects, have all been found to be Br-positive, and in addition 5 Br-negatives selected from a different panel from the 69 *Rh*-negatives have been found to be *Rh*-positive.

The Rhesus genotypes of eight Br-negatives, including H.Br. himself, were determined by Dr R. Race and the late Dr. G. L. Taylor. Seven, including H.Br., fell into the class including *Rh*₂*Rh*₂ and *Rh*₂*rh*, and one was *Rh*⁺*rh* or *Rh*⁺*Rh*⁺. The father and only child of H.Br. were found to be respectively *Rh*₂*Rh*₂ or *Rh*₂*rh*, and *Rh*₁*Rh*₂, both Br-positive.

Some Br-positives are extremely weak reactors with the rather low-titre specimens of serum now in use, and it appears probable that a few of the apparent negatives would react positively with a stronger serum. Nearly all the weak reactors tested for their *Rh* genotype have contained the gene *Rh*₂ or *Rh*⁺. *Rh*-negatives are almost invariably among the strongest reactors.

These properties are consistent with those of the antibody η predicted by Fisher¹. η should agglutinate the cells of all *Rh* genotypes containing the genes *Rh*₁, *Rh*⁺, *Rh*₂ and *rh*, but not those of genotypes composed exclusively of *Rh*₂, *Rh*⁺, *Rh*₂ and Fisher's hypothetical *Rh*₃. Thus most of the negatives will belong to the genotype *Rh*₂*Rh*₂, and *Rh*₂*Rh*⁺ and *Rh*⁺*Rh*⁺ will also be unagglutinated. As stated above, eight subjects negative to Br have been tested with the four antibodies in previous use. If Br is the hypothetical antibody η , then at least 85 per cent of Br-negatives should fall in the class containing *Rh*₂*Rh*₂, which constitutes no more than 15 per cent of the population. Of these eight cases, seven in fact fall in this class. None should fall in the group of classes which does not react to anti-*Rh*₂ or H—none in fact has been found to do so. The proportion of η -negatives should be 2.9 per cent, which is in fair agreement with the 4.1 per cent found for Br, a figure almost certainly including a few false negatives due to the weakness of the serum.

In order further to test this hypothesis, use was made of a family at present under genetic investiga-

tion, where two members are unambiguously *Rh*₂*Rh*⁺ and one *Rh*₂*rh*. The former are both Br-negative and the latter Br-positive. These genotypes were formerly serologically indistinguishable.

The genotypes of strong and weak reactors respectively show that the Br reaction is stronger where two Br-positive genes are present than where there is only one. In showing this single- and double-dose effect, Br resembles *St*^{2,3}, the other antibody known to agglutinate *Rh*-negative cells.

There can thus be little doubt that Br is identical with η , but genetic studies are continuing which should further confirm their identity. The chief practical value of the serum will lie in distinguishing between the genotypes *Rh*₂*Rh*₂ and *Rh*₂*rh*, the only common ones not distinguished by formerly known sera. The distinction is especially important in the fathers of erythroblastotic babies, since the *Rh*₂*Rh* men will have a much smaller chance of begetting healthy offspring than will *Rh*₂*rh* men. The discovery of this serum following soon after Race's discovery of the gene *Rh*₂^{3,4} emphasizes the value of Fisher's theory as an instrument of prediction.

This work would not have been possible without the help of the late Dr G. L. Taylor, who carried out most of the genotyping and gave me much very useful advice. Just before his untimely death, he was engaged in testing the serum against known genotypes and he appeared to have reached full agreement with the conclusions here stated. I am indebted to facilities for this work and much valuable assistance to Dr. H. F. Brewer, Prof. R. A. Fisher, Mr. R. Hudson and Dr. R. R. Race. My thanks are also due to Prof. R. V. Christie for the opportunity of investigating the patient concerned.

Anti-*Hr* Serum of Levine

In 1941, Levine¹ in New York described a rare type of anti-*Rh* serum which was called anti-*H*. This antibody was found in the serum of an *R*⁺ positive mother of an erythroblastotic infant. Unfortunately, the weakness of the antibody did not allow the genetics of its corresponding red blood cell antigen to be worked out.²

In 1943, a powerful antiserum now called *St* was found in England and the genetics of the antigen which it recognized were worked out.^{3,4,5,6} Anti-*E* and *St* sera were alike in that they both reacted with *Rh*-negative and with at least the majority of *Rh* cells but here the similarity ended. Wiener, however, has categorically stated that they are the same antibody.⁷ A powerful example of anti-*H* serum has now been found and has recently been described by Waller and Levine.⁸ From the description it is quite clear that anti-*H* and *St* are not the same antibody. Waller and Levine say "in tests with potent anti-*H* serum all the *Rh*₁*Rh*₂ bloods gave negative reactions. About 60% of *Rh*₁ bloods of white individuals and almost all coloured individuals tested possessed the *H* factor." The original serum and three identical sera in our collection c

react with all Rh_1Rh_2 bloods. It is a striking coincidence that the percentage of positive reactions in the Rh_1 group corresponds exactly with the percentage which we can recognize by means of St serum to belong to genotype Rh_1rh , and it seems highly probable that this potent anti- Hr serum agglutinates the Rh_1rh fraction of the Rh_1 group. If this is so, it must react with only a single dose of an St positive gene, and the failure to agglutinate Rh_1Rh_2 cells cannot be attributable to the presence of only a single St -positive component, namely, Rh_2 .

It is interesting to compare the observed reactions of this potent anti- Hr serum with those predicted for the hypothetical antibody δ which Fisher's formulation anticipated⁶

Genetic structure in Fisher's scheme	Rh -negatives cde	Rh_1Rh_2 CDe	Rh_1 blood of white individuals About 60 per cent Rh_1rh and 40 per cent Rh_1Rh_1 CDe	Rh_1Rh_2 CDe
Observed reactions of anti- Hr (Levine)	+	-	+ with "about 60%"	-
Predicted reactions of δ (Fisher)	+	-	+ with Rh_1rh (60 per cent)	- with Rh_1Rh_1 (40 per cent)
Observed reactions of St (or γ)	+	+	+ with Rh_1rh (60 per cent)	- with Rh_1Rh_1 (40 per cent)

The hypothetical δ reacts with δ St (or γ) reacts with c

It was realized when Fisher proposed his scheme that if the antibody δ were encountered, it would be easily distinguishable from γ because the former would fail to agglutinate Rh_1Rh_2 cells.

The finding by Levine of an antibody possessing the characters of one predicted in Fisher's formulation of the genetics of the Rh blood groups greatly increases the probability that this formulation represents the actual state of affairs. That St serum and Levine's anti- Hr serum contain quite different antibodies is now certain, both react with Rh -negative blood, but with different components in its antigenic constitution.

It seems probable that Levine and Wiener are working with different anti- Hr sera. Levine's powerful anti- Hr appears to be the predicted δ , while Wiener's is probably St (γ).

Waller and Levine, *Science*, 100, 453 (1944)

With the complete set of six antibodies now apparently discovered, the recognition of rare genotypes will be immensely easier. All the homozygotes of the seven known allelomorphs can be distinguished unambiguously, and nine of the heterozygotes, namely (omitting h 's), R_0r , R_0R_2 , R_0R_1 , R_2R'' , R_2R_2 , $r'r$, R_1R_2 , R_1R' . Three pairs of heterozygotes are indistinguishable

R_0R''	R_0R'	R_0R_2
R_2r	R_1r	R_1R_2

These leave little practical doubt, since in each case the genotype printed below is about one thousand times more frequent than that above.

Three more heterozygotes are capable of confusion only with a heterozygote involving R_y , which has not been discovered, and is unquestionably very rare.

R_yR_2	R_yR_1	R_yr
R_2R''	R_2R'	$R'R''$

It is among these that R_y may be looked for.

Finally, a group of three known genotypes, and one involving R_y , should react positively with all six reagents. These with their approximate frequencies in the British population are shown below.

R_1R''	R_2R'	R_2r	R_0R_y
0.8%	0.3%	0.4%	very rare indeed.

Thus it is only among these last that genotype recognition will have to rely on pedigree evidence. The interpretation of pedigree evidence also will now be greatly facilitated.

An Unsuspected Relationship between the Viruses of Vaccinia and Infectious Ectromelia of Mice

It has been observed that emulsions in saline of the lesions produced on the chorioallantois by the virus of infectious ectromelia of mice have the capacity of agglutinating fowl erythrocytes. As is the case with vaccinia virus preparations¹, only about 50 per cent of individual fowls provide susceptible cells. Cells susceptible to one virus are susceptible to agglutination by the other. Agglutination by infectious ectromelia virus is inhibited by anti-vaccinal immune serum from calves.

The possibility of the infectious ectromelia virus being contaminated with vaccinia virus can be excluded, first by the completely different appearance of the lesions produced by the two viruses on the chorioallantois, and secondly by the fact that liver and spleen emulsions from mice dead of infectious ectromelia give a similar agglutination of susceptible but not of insusceptible fowl cells.

Using a technique similar to that commonly used for haemagglutination work with influenza virus, the titre of a stock membrane emulsion of ectromelia virus (each chorioallantois ground with 1 ml. of saline) is about 1×10^2 . The same emulsion titrated on the chorioallantois gives approximately 1.2×10^7 specific pocks per ml. This corresponds closely to the relationship found between the results with the same two methods of titration of vaccinia virus. Preliminary work suggests that a soluble product rather than the virus itself is responsible for the haemagglutination.

Although the two viruses differ sharply in host-range and type of lesion produced, their physical qualities agree closely, and there seems to be no adequate reason why our findings should not be taken at their face value as indicating that infectious ectromelia is the murine representative of the mammalian pox diseases.

Effect of Adrenaline Solutions on Oat Roots

A SOLUTION of adrenaline, which is a catechol derivative, oxidizes in the presence of air and much more readily when some phenolases¹ are present. Solutions of adrenaline in tap water can inhibit the growth of oat roots in the concentrations indicated below

Concentration of adrenaline Per cent growth value	0.001 M	0.0005 M	0.0001 M	0.00005 M
	59.4	75.8	83.8	97.3

In addition to the effect on growth as measured by extension of roots, certain effects on cell development are of note. After forty-eight hours growth in the more concentrated solutions, it was observed that the root cap, when viewed by reflected light, was jet black and by transmitted light dark brown in colour. Under the microscope the youngest part of the root was still light, and the crest of dark root-cap cells was an excellent demonstration of this tissue.

At the root base and extending down to the region of cell expansion, the piliferous layer was seen to be stained dark brown and the root hairs remained small or undeveloped. In addition, the normal expansion of the piliferous layer had been prevented so that splitting of this tissue had occurred exposing the relatively unstained underlying tissues.

It was observed that the cell walls of the piliferous layer were stained and often the outer wall of the exodermis, this latter tissue apparently performing its classical role as a selective barrier to substances in solution. The staining was almost certainly due to the more complete oxidation of the adrenaline by a phenolase from the root cells. Tests for oxidase in normal 48 hours old roots showed that with Nadi reagent a deep blue colour developed rapidly in the root cap and root hairs and in the root generally. In the presence of peroxide the catalase of the root caused a rapid evolution of oxygen.

Control of the Potato-Root Eelworm *Heterodera rostochiensis* Wollenweber, by Allyl Isothiocyanate

MORGAN¹ was the first to report that few eelworm cysts are found on the roots of potato plants grown together with white mustard in pots of soil infested with the potato-root eelworm. Afterwards² it was shown that root excretions from potato plants mixed with those from white mustard seedlings will no longer stimulate the emergence of eelworm larvae from the cysts, this effect is also produced by black mustard, perhaps by cress, and, by certain solutions of allyl isothiocyanate, the mustard oil of black mustard seed³. Field trials with white mustard as green manure were a failure^{4,5}, due, it has been suggested⁶, to the difficulty of applying the excretions in sufficient quantity in the field, the results with allyl isothiocyanate suggested that these difficulties might

be overcome, and a small-scale field trial during 1944 gave promising results.

The mustard oil, on granular peat, was applied to the potato drills at the time of planting. Treated plants were superior to the various types of control throughout the season, and the difference became more pronounced as the season advanced. Yields were about 100 per cent above controls and the differences were statistically significant.

This is not the first occasion on which isothiocyanates have been used in combating eelworm. Smedley⁷ found the phenyl form to be very toxic to the eggs in the cysts, and used it in an extensive field trial, apparently unaware of the early work with white mustard and of the possible connexion of isothiocyanates with the response of larvae to potato root excretions, the oil, adsorbed on to talc, was applied all over the treated plots some time before planting. Comparison of the results of my experiment with 160 plants with those from an extensive field trial is somewhat presumptuous, but the results are very different. Application of phenyl isothiocyanate at the rate of 2 cwt. per acre increased the yield by 35 per cent, smaller dressings were ineffective. On the other hand, allyl isothiocyanate at the rate of only 0.1 cwt. or about 11 lb. per acre increased the yield by 100 per cent, and this isothiocyanate is also far cheaper. It remains to be seen whether the greater effect of the latter is due to the method of application, which takes account of the 'interaction' between mustard oil and potato root excretion, or whether it is due to difference in the properties of the substances.

A detailed account of this work will be published elsewhere.

Use of Calomel on Onions

THE observations of Dr J. R. Boorer on the control of onion white rot (*Sclerotium cepivorum* Berk.)¹ are very interesting. A fairly extensive experience in the use of mercurous chloride for onion seed treatment under field conditions has led me to believe that the use of this substance may have a wider significance than is realized.

A particular case may be noted. During 1943 and 1944, I had under observation plots of onion plants grown from seed which had received calomel treatment at the rate of $\frac{1}{2}$ lb. per lb. of seed. In these plots I was surprised to see what appeared to be a marked degree of control of eelworm (*Anguillulina dipsaci* Kuhn), and a marked improvement in the crop itself.

Laboratory tests using calomel in water are entirely negative so far as any lethal effect on eelworm is concerned, but Dr Boorer tells me that his opinion some lethal effect is not impossible when calomel is decomposed in the soil. If this is so, a further investigation confirms that some degree

control of eelworm may be obtained, and this in addition to the already established control of onion fly and onion white rot, it would seem that the use of calomel in respect of onion crops may be very valuable.

Insect Epicuticle

Alexander, Kitchener and Briscoe^{1,2} have shown that the desiccation of many insects caused by inert dust insecticides is due to adsorption of the epicuticle wax film, which becomes discontinuous and allows of increased loss of water through the cuticle. Further, Wigglesworth^{3,4} has demonstrated abrasion of the wax film and increased evaporation of water caused by the application of an inert dust. It is evident, however, that insects differ considerably with regard to the epicuticle, for nymphs of *Rhodnius* are unaffected by adsorption but are susceptible to abrasion³, whereas *Tenebrio* and other larvae are more susceptible to adsorption than to abrasion¹.

Experiments with 'Neosyl' (a proprietary adsorbent silica dust) and carborundum powder show that *Sarcophaga* larvae are affected neither by adsorption nor abrasion, suggesting that they differ from both *Rhodnius* and *Tenebrio* larvae with regard to their epicuticular waxes. Histological examination shows that lipid substances are confined to a very thin layer at the surface of a thin (4μ) protein epicuticle. This surface layer differs from the remainder of the cuticle in being insoluble in cold concentrated hydrochloric acid, and may therefore be isolated as a thin membrane. Prolonged treatment with lipid solvents does not destroy the ability of this membrane to stain with Sudan Black B, and on account of its integrity after these treatments it is justifiable to regard it as a constituent layer of the cuticle, the outer epicuticle consisting apparently of a very stable lipo-protein complex. The bulk of the protein epicuticle does not stain readily with Sudan Black B, and is almost completely untanned.

A similar double epicuticle is present in the cockroach *Periplaneta*⁵, which also possesses an external layer of labile fatty substance⁶. It seems, therefore, that lipid substances may be associated with the insect epicuticle in one or more of a number of ways. They may be present as a readily removable surface layer; they may form a complex with the surface of the epicuticle so as to produce a distinct structural layer; and they may impregnate the whole of the epicuticle when this layer is tanned⁷. Variations in lipid distribution in the cuticle must clearly be taken into account as one of the many factors determining the effectiveness of an inert dust insecticide on different insects.

Units for Degree of Vacuum

It has long been considered in this laboratory that when working in the field of medium and high vacua (pressures of 1 mm. mercury or less), the usual methods of referring to and recording the degree of vacuum are extremely awkward verbally and little less so when written.

There are a number of known systems of recording such pressures, the bar and the millimetre of mercury pressure (mm. Hg) and their subdivisions being most widely known, the micron being a subdivision of the mm. and the Torr, found in German practice, being a name given to the millimetre of mercury pressure as a unit of pressure. The millimetre of mercury pressure is almost universally used, but when subdivisions of this unit are used, recourse is necessarily made to either the negative index method or the decimal method of reference or recording. Thus, a pressure of, say, 2×10^{-5} mm. mercury may be written so, or as 0.00002 mm. Hg; both methods are lengthy to write, but verbally these expressions are even more unwieldy.

It is proposed, therefore, that a new unit be adopted, based on the logarithm of the numerical value of the pressure in millimetres of mercury. The reading in these units is, in fact, the logarithm of the pressure in millimetres, reduced to its all-negative form and multiplied by minus 10, this being similar to the method of measuring power ratios, etc., in decibels, the reference-level in this case being 1 mm. mercury pressure. A scale formed on this basis is very simple in use, both for written record and verbal reference, resulting in pressures of 10^{-1} , 10^{-2} . . . 10^{-6} mm. mercury, etc., becoming vacua of 10, 20 . . . 60 units, etc. The pressure of 2×10^{-5} mm. mercury referred to becomes a vacuum of 47 units. This system also leads to the logical result, that a 'higher' vacuum has a higher numerical value.

Such a system as that suggested could, of course, be based on any other unit of pressure, such as the bar or the standard atmosphere; but it is considered that the basic level of 1 mm. mercury pressure gives the working-range fitting best with current practice. Also a pressure of 1 mm. mercury is, in a most marked manner, the border-line between the field of medium- and high-vacuum work and the field of low-vacuum work, and there is seldom any overlap between the two fields. Consequently the fact that a pressure of greater than 1 mm. mercury would have a negative value on the suggested scale is of little disadvantage, since where work is consistently done in the low-vacuum range it is recommended that the scale of millimetres be adhered to.

FIG. 1. SCALE OF TYPICAL MCLEOD GAUGE. FULL SIZE.

Fig. 2. SPEED OF 3-STAGE MERCURY DIFFUSION PUMP AT DIFFERENT VACUA.

A typical McLeod gauge scale, calibrated in the suggested manner, is shown in Fig. 1, and it may be seen that a more evenly marked scale than usual is obtained. Curves of pump performance, etc., may be plotted on ordinary squared paper, as shown in Fig. 2, and in both cases intermediate values may be more accurately interpolated than by the usual method.

No name has been given to this unit, as it has been found that reference to 'a vacuum of 47' is sufficient once the system has been established, but should this suggestion become more widely adopted, a suitable name should be found.

Reflexion in a Non-Isotropic Medium

THE way in which the extraordinary ray transmitted by a calcite crystal infringes the laws of simple refraction is, of course, a commonplace and is mentioned in all text-books that deal with polarization.

Fig. 1.

On the other hand, I have not yet found an explicit reference to the infringement of the law of the equality of the angles of incidence and reflexion.

Hence the accompanying photograph (Fig. 1), which illustrates one simple case, may be of interest. It shows the trace, on a sheet of paper, of a ray of unpolarized light incident upon the totally reflecting face of a prism of calcite cut in such a way that the optic axis is parallel to the incident beam. Two plane polarized rays are reflected. The one reflected normally is the ordinary ray, with the electric vector perpendicular to the plane of the paper, whereas the one reflected at an obtuse angle is the extraordinary ray with the electric vector parallel to the plane of the paper. In the latter case it is clear that the angle of incidence made with the totally reflecting surface is not equal to the angle of reflexion.

Fig. 2.

The result follows, of course, from the fact that, in the time waves take to travel from *P* to *Q* in Fig. 2, the extraordinary wave front that spreads out from *S* is an ellipse, and the reflected ray is thus propagated in the direction of the arrows or the tangent *QR*. After refraction this ray gives rise to the emergent ray seen in the photograph. The path of the ray thus calculated (using the accepted values of the ordinary and extraordinary refractive indexes) is in good agreement with the observed path.

Action of Hydroxylamine on Polysaccharides Oxidized with Periodic Acid

BARRY¹ discovered that when a polysaccharide has been oxidized with periodic acid, the oxidation product on warming with phenylhydrazine yields glyoxalosazone. Thus, oxidized starch and cellulose are, theoretically at least, completely broken down into glyoxalosazone and erythrose phenylhydrazone while 1,3 polysaccharides, such as laminarin, being attacked only at terminal units by periodic acid have these oxidized terminal units completely removed by phenylhydrazine. It has now been found that a similar reaction takes place with hydroxylamine. Starch oxidized with periodic acid quickly dissolves in boiling water or absolute alcohol on addition of an alcoholic solution of hydroxylamine made by adding alcoholic potash to hydroxylamine.

hydrochloride until the solution is faintly alkaline. The solution becomes faintly acid as the starch dissolves and must be brought back to alkalinity by addition of more alcoholic potash. When the solution of the starch is complete, except for a small residue, the solvent is evaporated off, and ether will extract glyoxime from the residue after acidulation to set it free from its potassium compound.

Harriss² found that when the semiacetal of glyoxal, $\text{CHO}-\text{CH}(\text{OC}_2\text{H}_5)_2$, was treated with phenylhydrazine, an oily phenylhydrazone was formed, and when the mixture was heated, the acetal group also reacted with production of glyoxalosazone. An inspection of the formula for the oxidation product of starch with periodic acid shows that it is a polymerized semiacetal of glyoxal and erythrose, so that Barry's reaction is a special case of that of Harriss. Harriss does not report any attempt to form glyoxime from his glyoxalsemiacetal, but no doubt such a reaction would take place.

The yield of glyoxime from an oxidized starch has not so far been as good as the yield of glyoxalosazone, and has not exceeded about 30 per cent of that theoretically obtainable on the assumption that each unit of the starch has been oxidized. If, by further experiments, the yield can be made quantitative, the 'cleanness' of the reagent should make the oxime reaction a useful weapon for elucidating the structure of polysaccharides.

Mechanism of Felting of Wool Fibres

THE theory of felting of wool in fabric form developed by Speakman and his collaborators¹ postulates that under the repeated application of pressure the unidirectional migration of wool, due to its scaly surface, is achieved by local extension and contraction of the fibres, and conditions which favour these processes promote milling shrinkage. In the course of the present investigations, a full account of which will appear elsewhere, it became clear that in felting the frictional properties of wool are as important, if not more so, than its extensibility and power of recovery.

The reason why the fibres always travel in the direction of their root ends in milling is that the action of wool is greater when rubbed from tip to root than from root to tip². The difference between the maximum and the minimum coefficient of friction has been termed by Martin³ the 'directional frictional effect', and it has been determined in the present experiments for a uniform sheet formed by several hundred wool fibres, with their scales all pointing in the same direction, against a horizontal polished

glass surface immersed in the appropriate medium. Some of the results, all relating to the same fibres, are given in Table 1, from which it is evident that the directional frictional effect changes with the pH of the medium in the same sense as does the felting power of wool.

These figures indicate, therefore, that the directional frictional effect is a very important factor in felting over this pH range, and in point of fact the recent communication of Whewell, Rigelhaupt and Selim⁴ partly confirms this conclusion, although they still maintain that in alkaline solutions the elastic properties alone determine the felting power of wool.

The same authors⁴, and Martin³, showed that the success of the anti-felting treatments with such reagents as chlorine, sulphuryl chloride, proteolytic enzymes, etc., depends on their ability to reduce the directional frictional effect of wool fibres. On the other hand, it has recently been claimed by Bari and Speakman⁵ that benzoquinone and mercuric acetate are the two substances which, in contrast, reduce the felting power of wool solely by modifying its elastic properties, which was also suggested earlier⁶ to be the cause of the diminished shrinkability of woollen fabrics dyed with heavy concentrations of certain dyestuffs.

We were not able to confirm the latter observations when the directional frictional effect of fibres treated with mercuric acetate, benzoquinone and 50 per cent Solway Green GS, respectively, was measured in soap solution using the present method, as distinct from the violin bow or the so-called lepidometer employed by Speakman and his collaborators. The results, which are summarized in Table 2, show clearly that in each case the anti-felting treatment has led to a very considerable reduction in the directional frictional effect.

TABLE 2*

Treatment	Maximum coefficient	Minimum coefficient	Directional frictional effect
Untreated	0.5333	0.4863	0.0470
Benzoquinone ⁵	0.6191	0.6121	0.0070
Untreated	0.5037	0.4634	0.0403
Mercuric acetate ⁴	0.6057	0.5957	0.0100
Untreated	0.2642	0.1837	0.0805
50 per cent Solway Green GS	0.4337	0.4047	0.0290

* The figures for each treatment refer, of course, to different sheets of fibres. The first two sets of results were obtained in 0.25 per cent soap solution, while the figures for the Solway Green GS treatment relate to 1 per cent soap solution.

Wool felts only to an insignificant extent in the absence of aqueous media, and this fact has been found to be also closely associated with the frictional properties of wool. Thus the directional frictional effect in ordinary air of air-dry fibres and of fibres immersed in lubricating oil has been discovered to be very low compared with the directional frictional effect of the same wool in an aqueous solution, as Table 3 shows.

TABLE 3

Medium	Maximum coefficient	Minimum coefficient	Directional frictional effect
Water	0.5000	0.4545	0.0455
Ordinary air	0.2060	0.1806	0.0254
Lubricating oil	0.3652	0.3453	0.0199

To sum up, these three sets of results indicate that (1) the variations in the felting-rate over the pH

TABLE 1

Medium	Maximum coefficient	Minimum coefficient	Directional frictional effect
Hydrochloric acid (pH 0.63)	0.4428	0.3559	0.0869
Soap (pH 9.87)	0.3559	0.3014	0.0545
Borax (pH 9.20)	0.4486	0.3968	0.0518
Sodium carbonate (pH 9.90)	0.5815	0.5321	0.0492
Water (pH 8.40)	0.5000	0.4545	0.0455

range in unbuffered solutions are directly related to the changes in the directional frictional effect, (2) apparently all known anti-felting treatments cause diminution in the directional frictional effect, although it is possible that the ability of some of these reagents to increase the resistance to deformation of the fibres contributes to their efficiency by rendering fibre entanglement more difficult, and (3) the low felting power of wool in non-aqueous media is due to their apparent incapacity to enhance the directional frictional effect.

It would appear, therefore, that the peculiar frictional properties are a principal, if not the principal, governing factor in the felting of wool fibres. The present evidence also suggests that their surface characteristics are of a more complex nature than hitherto supposed.

Rontgen Centenary

PROF J. A. CROWTHER in his interesting article on "Rontgen" writes as follows: "The use of X-rays in the treatment of disease has scarcely made such satisfactory progress as its use in diagnosis." With Rontgen's first skiagram, radio-diagnosis was born, but what *a priori* reasons were there for supposing that X-rays would have any therapeutic value? None at all I think, yet some courageous few entered the field of exploration, and can anyone say that the results have in the circumstances really been unsatisfactory? Thirty-five years ago, all the beds in the Cancer Wing of the Middlesex Hospital were occupied by inoperable cases of cancer, there was no treatment except an almost superhuman kindness. In 1939 there was not one among the 92 patients in those wards who was not receiving active treatment, and for the great majority of them the treatment was by means of X-rays and radium. Though it cannot be claimed that these agents are a cure for cancer, the development of radiotherapy can scarcely be called unsatisfactory.

Prof Crowther says later on in the same article, "The action of X-rays on tissue cells, whether healthy or diseased, is, it must be understood, always destructive." But is it so? Are the haemostatic action of X-rays, their power of producing a lymphocytosis, their resolution (not destruction) of scar tissue, their action in regenerating bone, their excitation of the bone marrow to unusual activity, their temporary hold-up of mitosis, their enhancement of the mutation-rate, are these all to be labelled as destructive?

Treatment by means of X-rays and radium is a subject in which we do well to think in a rather less restricted manner than Prof Crowther's article suggests.

SIDNEY RUSS

Barnato Joel Laboratories,
Middlesex Hospital,
London, W 1

PROF RUSS does well to be jealous on behalf of a subject which he has made peculiarly his own. I can assure him, if assurance is needed, that my admiration of the magnificent work both in the way of treatment and research which has been, is being, and will with ever-increasing success continue to be, done in our radiotherapy departments is no whit the less than his own. I am only surprised that anyone who has read carefully the whole paragraph of which Prof. Russ quotes the opening sentence should doubt it. "Unsatisfactory" is Prof. Russ's word not mine.

As regards my poor word "destructive" with which Prof. Russ quarrels, it all depends on whether one considers the immediate action of the radiation, or the long-distance results of the action. To take only the case of the production of mutations, which is one which we are just beginning to understand, the primary action of the X-radiation is to break a chromosome chain at two different points. This, of course, gives Nature its chance to arrange the pieces in a different order, nevertheless, the breaking of a chain is essentially a destructive action.

J. A. CROWTHER.

University of Reading

Problems of Nomenclature

I HAVE read with much interest the discussion in *Nature* of December 30, p. 812, and wish to add a few suggestions to those there given. In the first place, it is highly desirable to have a single code of nomenclature for plants and animals. The problems are the same in both cases, and the existing codes are so much alike that a very moderate amount of revision would be necessary to secure uniformity. There are two matters which cause confusion, and should be dealt with.

(1) *Nomina seminuda*—names which have been introduced in an informal manner, without proper descriptions, but have been taken up because they could be interpreted in the light of subsequent researches. It would be a dangerous policy to rule that names poorly supported by descriptions should be rejected, but when there is nothing which will distinguish the species, and only subsequent studies of the fauna indicate by the locality what was referred to, the name should be rejected.

(2) Names proposed as of lower than specific rank. It should be ruled that subspecific names have the same validity as specific, that is, if a form is proposed as a subspecies, but later raised to specific rank, the subspecific term should be used. This is the usual practice, at least in zoology, but the botanists have mixed subspecies and individual variation under the designation 'variety', and it is not always easy to determine what the author had in mind. I would be well to take the lists of so-called varieties and separate those names which were really intended for what zoologists call subspecies, rejecting the others as invalid for use as species names.

In such ways a good many really needless changes might be avoided. A very desirable reform in botanical writings is the dropping of the name of the author of the combination in ordinary references to plants. Such names are scarcely ever cited in zoology, and I cannot recall an instance in which their omission has caused any inconvenience. The botanical practice wastes a lot of printer's ink and paper.

Palm Springs,
California

SCIENCE MASTERS' ASSOCIATION ANNUAL MEETING

THE annual meeting of the Science Masters' Association was held in the Science Department of the City of London School during April 9-11.

The presidential address by Mr C L Bryant, late of Harrow School, and now, in his own words, of Ferranporth Youth Club, dealt with "The Impact of Science on Human Beliefs". The theme was worthy of one who, for nearly forty years, has served the Association faithfully and well. Christian missions are criticized because they uproot the faith of the natives without planting anything more suitable in its place. Science is doing that here and now. Until about fifty years ago, men believed, more or less, what the Churches told them. Now, for the most part they believe in nothing at all, not even in science, except as a provider of luxuries. This is largely because there is no background of philosophy to the science which is commonly taught in schools. Many of the Churches are hampered by creeds in which minor and debatable points are magnified into articles of belief. It is difficult for a scientific layman to discuss such matters with ecclesiastics. In the interests of truth the barriers should be broken down, and Mr Bryant pleaded for an approach between science and religion for (as we have recently seen) "where there is no vision the people perish". A group of members under Mr Bryant's leadership is to tackle the problem.

"The Social Relations of Science" was the title of the Science and Citizenship Lecture given by Mr J G Crowther, of the British Council. Mr Crowther traced the development of scientific research from the small scale activity before the War of 1914-18 to its present highly organized state, and outlined the consequent revolutionary changes in the place of science in the life of mankind in the last twenty years, and foreshadowed the equally great developments to be made in the next twenty years. Where are the men of science to come from to stimulate the application of science to many aspects of life in Britain? That is an educational problem. One of our chief tasks is to use the ability and enthusiasm of men of moderate ability much more efficiently than at present. In the education of such men the science master should be given every encouragement and material assistance, and such education should include a thorough study of the relation of science to other human activities. The men we need should be "statesmen of science" who approach the problems of humanity with the knowledge and understanding of statesmen, statesmen who approach them with knowledge and understanding of science.

A large audience was privileged to hear Sir Alexander Fleming describe his discovery of penicillin and the subsequent researches which led to its manufacture and chemical use. By means of an excellent series of lantern slides he led his audience through years of patient researches with a clarity of exposition that enabled each to feel the thrill of discovery. He described the work of the chemists in isolating the pure substance and the skill with which they overcame the major obstacle of its instability. No written account could do justice to a lecture which combined lucidity with dry humour and conversational intimacy.

Mr J McG Bruckshaw, of Imperial College, spoke on "Physics and Economic Geology" and gave a clear outline of the application of physics to the

problem of locating mineral deposits. Mr F W Cuckow, of the National Physics Laboratory, gave a fascinating account of the development and scope of the electron microscope, members enjoyed the speaker's intimate style and an excellent series of lantern slides. Mr R Maitland dealt with the chemistry of plastics, including an account of the replacement of carbon by silicon in the giant molecule. Mr C Bibby, education officer, Central Council for Health Education, talked eloquently on health education through school biology. The importance was stressed of distinguishing between habits which were the disciplining of natural functions and those aesthetic habits which were really habits of civilization.

A film show and discussion was held in the Ministry of Information theatre. Mr Arthur Elton, president of the Scientific Film Association, opened by speaking on the scope and limitations of the science teaching film. Scientific films of a suitable nature were few, and he thought that it was the duty of the teaching profession to lay down their policy for films in collaboration with the Scientific Film Association—the kind of films they wanted and for what age-groups. Science films, including the "Transfer of Power" which was produced and directed by Arthur Elton and Geoffrey Bell, were shown. Mr Geoffrey Bell discussed the film critically in a short talk on the making of a film. He stressed the need for careful research and script, good production and skilful editing, and invited the co-operation of members in helping to make good films. Mr W Farr, head of the Central Film Library of the Ministry of Information, spoke on the distribution of films. He hoped to see a Central Film Library linked with a number of local libraries—possibly twelve regional libraries dealing with free distribution of educational films to schools. Many members took part in the subsequent discussion. It was agreed that the best equipment for a school was one sound projector for use in the main hall plus one or more smaller silent machines for classroom use. A plea was made for using teachers not only in suggesting titles and the contents of scripts but also in the production of films and in getting better commentaries. The various types of films needed—historical, revision, etc—were discussed and the relative advantages of film and film strip assessed. Members were pleased to learn that the Education Section of the Scientific Film Association were engaged in preparing lists of suitable films and of the offer of Imperial Chemical Industries, Ltd, to produce scientific films for purely educational purposes.

A general discussion on the role of science in the future educational system was opened by Mr A W Wellings (Leamington College) and Mr D H J Marchant (Ilford County School). Mr Wellings, after examining the criticism of existing science teaching, stressed the great opportunities for the Association to see that, within the general educational framework provided under the new Act, science teaching plays a vital part in preparing pupils for the difficult and exciting job of living in a rapidly changing world. He pleaded for emphasis on the adventure of science, and for an alteration in technique, and a new attitude, so that the pupils get a better idea of the way in which science affects human activities and progress at every point, and can be led to realize that the problems created by science will be, in part, theirs to solve. He gave suggestions how this could be attempted, including a plea for a re-orientation of chemical studies, so that they could

be taught from the point of view of natural resources Mr Marchant dealt with the content of science courses. He advocated general science for all types of school, but emphasized that, although the course should cover a fairly wide field, whatever is taught must be science. He offered valuable suggestions on the elimination of irrelevant matter and on the economy of time and effort by presenting subjects with due consideration of the stage best suited to the difficulties. In developing theories, the tempo should not be that of research workers but accelerated in proportion to the richer background of fact which may now be assumed. Syllabuses should be planned concentrically so that general science and its possibilities for good could be worked out. Many members made valuable contributions to the discussion. Practical points such as the time allocation for science teaching (where the subject is taken to two credit stage in the School Certificate the allowance should be the same as for two separate science subjects), laboratory equipment, the relation between pre-school certificate work and post-school certificate studies, and courses for teachers. A plea was made for a fundamental approach so that science can be seen in proper perspective in the whole education of the future man. It was interesting to note, as distinct from pre-war discussions, that members seemed to assume that it was general science, and not separate science subjects, to be discussed.

The Members' Exhibition, though smaller than in recent years, was up to its usual high standard, and visits were made to hospitals, newspaper offices, the General Post Office and other places of scientific interest.

MARINE AND OTHER BIOLOGICAL LABORATORIES

By PROF. J. H. ORTON
University of Liverpool

DURING the war years, there have been a number of communications in *Nature*¹⁻⁴ on marine biological laboratories. It is possible that a review of these may be useful at the present time.

Great Britain

For many decades the Marine Biological Laboratory at Plymouth has been the centre of fundamental marine biological research in Great Britain, it has been the Mecca of zoologists from most British and many foreign universities. The chief reasons for the success of Plymouth are as follows. First, the abundance and variety of the fauna, the constituents and biology of which have steadily been defined by a succession of naturalists. The Laboratory was also able to supply research material at all times. The accessibility of Plymouth from the situation of the older universities was also important. The policy of the director, which pervaded the staff, has always been to hold to the principle that visiting and other researchers must be supplied with whatever living or other material they needed for their researches, so far as it was in the power of the staff and station to supply it. The policy of the Council has been to attract the nascent generation of zoologists as students of courses in marine biology, including ship and shore expeditions, and so to display the attractions of the subject and the station, and bring

together researchers working on a variety of problems. Lastly, sustained and increasing support was given by governmental departments, and especially the Development Commission, to the Laboratory.

Thus, a visiting researcher knew from the published fauna list⁵ what animals—or plants—he could expect to get in a living condition, and also that he would be given every reasonable help to conduct his researches. In the circumstances, a great variety of workers was attracted to the station, and their publications⁶ show that investigations have been made over the whole range of biology, namely: morphology, systematics, embryology, growth, life-history, food and mode of feeding, digestion, general physiology, sex and breeding, variation and heredity, ecology, behaviour and mortality, as well as the more limited and special problems of marine biology.

With this perspective in mind, it is easy to understand the growing need of the newer universities—less conveniently situated to Plymouth than the older—for a laboratory in proximity to them where facilities for study comparable to those at Plymouth can be attained.

Marine biological laboratories have also been established at Port Erin (University of Liverpool), Millport (University of Glasgow), Cullercoats (University of Durham), St Andrews, Nigg (University of Aberdeen), Robin Hood's Bay (University of Leeds), the Government stations at Lowestoft and Conway, Lough Ine (University College, Cork) in Eire, while the Welsh universities are also requiring one at Bangor. There is undoubtedly scope of some kind for all these stations, if scope be defined as facilities for visiting researchers, for special marine biological researches and provision for student vacation courses. All these laboratories, except Lowestoft and Conway, differ from that at Plymouth in belonging to universities, and as such had to compete in pre-war years with other departments for the limited funds available, or be dependent upon external sources for existence, but as the external source was mainly the Development Commission (Advisory Committee on Fishery Research), which quite correctly gave its major support to the definitive research station at Plymouth, there was little financial support left for the university marine laboratories.

The question now arises what functions these laboratories are to serve in post-war years. In a long-term policy, are the prospects in marine biological research such as to justify the staffing of all these laboratories with research workers? If the staffs were provided, would they find an adequate outlet for their energies and careers, and also supply in a succession of personnel the needs for fishery and other research posts (including economic and industrial requirements) of Britain and the British Empire? The answers to these questions of policy are not simple. If we look no further ahead than twenty years, probably the answers can all be given in the affirmative. There is, however, need for caution in their own interest against over-production of marine biologists in the post-war years.

There is no doubt that all the university marine stations can pay handsome dividends for facilities for research in general biology, and for that familiarization of senior and junior students with the problems of living marine animals and plants and their habitats which constitutes for most students the most attractive part of a biology course. To this end it is necessary to maintain at least skeleton staffs in all stations.

Thus the claims of the different university stations

staffing will depend upon the functions assigned to them, the propensities and personalities of the associated biology departments, the suitability of the stations for marine research, and the accessibility of the stations. As all the stations have a common objective, a definite degree of association is necessary for co-operation in common problems, but it is imperative that each station be given freedom to follow in the main its own line of fundamental research.

At most of the stations, including Plymouth, the main bearing of the research has been zoological or planktonic. Prof F E Fritsch³ has directed attention to the field of research in Great Britain on the benthic flora, and the need for combined work by biologists, botanists and physiologists on benthic problems. In this regard Fritsch points out that the larger staff at Plymouth—and, we can add, the cumulative knowledge of chemical and physical factors in the environment—points to Plymouth as the centre for this work. It has, however, perhaps been overlooked that an extensive bionomical survey⁷ has been made of the littoral algae in the Port Erin locality which, along with the similar survey⁸ of the fauna, places the Port Erin station in a strong position for further development.

Freshwater Biology

In the development of biology in the future it is clear that freshwater biology is of increasing importance. The development of the research station of the Freshwater Biological Association at Wray is following closely that of Plymouth in marine biology, and a glance at its publications⁹ shows that, besides pure freshwater problems, fundamental researches are being carried out as well as the training of senior students. Freshwater biology of great importance in the training of teachers in biology, since most teachers are located in inland situations and can more easily obtain living freshwater than marine material for their pupils, who, moreover, can collect the material for themselves. A bulk of biology students in most universities is destined to become teachers, therefore every university will in the future sooner or later need some kind of laboratory adjacent to the university where freshwater problems can be studied. Those universities in inland situations—and indeed many schools—may very well find a freshwater station more useful than a marine station, and a freshwater station can easily be improvised and equipped at a relatively low cost.

Colonial and Foreign Marine Biological Laboratories

The correspondence in *Nature*^{1,2} has shown that the training of marine biologists for tropical service posts, and research—and for general experience—a marine laboratory situated in the tropics would be of great value. There can be little doubt that most universities would welcome the opportunity of sending students and staff to such a tropical laboratory.

But so far the possibility of establishing a marine laboratory in a sub-polar locality has not been explored. It is likely that results of as great, or even greater, general interest would result from researches at such a station both on scientific and especially on very economic problems. We know very little of the living conditions of marine organisms in latitudes of extreme cold, as expeditions to those parts have

necessarily been mainly concerned in bottling their catches. New technique would be required and would be produced.

The Icelandic and White Sea fisheries present large economic problems, but general biology offers a wider and almost unknown field. The Danes, Russians (especially Gurganova¹⁰), as well as the British in the "Discovery" Investigations, have approached the problems, and would be interested in a station of this kind, which might indeed have an international character.

A site in Iceland or the east coast of Greenland, in addition to any the Russians may establish in the region of the White Sea, would, it is hoped, be accessible by air in post-war years, it would offer as great attractions as the tropics to adventuresome researchers.

RIPENING EFFECTS OF EMANATION FROM FRUITS

BECAUSE the emanation from ripe fruits will accelerate the ripening of unripe fruits, it is in general undesirable to store together fruits of many varieties which have normally different rates of ripening, as the early ripening varieties may induce an undesirable hastening of the ripening processes in longer keeping types. It is of interest, therefore, to note that R M Smock¹ finds that the stimulating effects are greatest with emanations from apples past their climacteric, while the post-climacteric apples are themselves almost unaffected by emanations from ripe apples. Sometimes the emanation induces in adjacent fruits well-defined symptoms of ethylene injury², but *Penicillium expansum* growing in the store does not produce sufficient ethylene (or other stimulating substance) to affect the ripening of apple fruits.

Immature pears put into store straight after picking produce only very small amounts of ethylene, but their ripening and respiration can be stimulated by ethylene and then they themselves produce ethylene³.

So great can the stimulating effect of these emanations from ripe fruit be that in order to prevent, partially at least, accelerated ripening of the main bulk of fruit in a store, isolated early ripening individuals are frequently removed from store by hand picking. R M Smock⁴ finds, however, that oiled paper wraps are helpful in protecting apples against emanations of other apples, but that this procedure is not so effective as the removal of ethylene from the air of the store, and this removal can be effected by the use of brominated active charcoal, prepared by fixing 5 c.c. bromine on 40 gm of coconut shell charcoal.

FORTHCOMING EVENTS

Monday, May 7

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4 p.m.—Prof F Davies "The Early Development of the Human Embryo" (Arris and Gale Lecture)

SOCIETY OF ENGINEERS (at Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p.m.—Dr V E Yarsley "Plastics in Engineering"

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (ELECTRICAL AND MECHANICAL ENGINEERS GROUP) (at the Austrian Centre, 69 Eton Avenue, Hampstead, London, N W 3), at 7.30 p.m.—Mr M Littmann "Neuere Erkenntnisse über Hartmetall-Schneidwerkzeuge"

Tuesday, May 8

SOCIETY OF CHEMICAL INDUSTRY (CHEMICAL ENGINEERING GROUP) (joint meeting with the INSTITUTION OF CHEMICAL ENGINEERS) (Geological Society, Burlington House, Piccadilly, W 1), at 2.30 p.m.—Mr L W Needham and Mr S Lynch "The Use of Suspensions as Heavy Liquids"

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 7.30 p.m.—Mr F C Grigg "The Mechanics of Chromosome Movements"

Wednesday, May 9

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Dr F M Walshe "The Treatment of Infantile Paralysis"

INSTITUTION OF ELECTRICAL ENGINEERS (TRANSMISSION SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Mr J H Savage "Localization of Faults in Low-Voltage Cables, with special reference to Factory Technique"

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W 1), at 5.30 p.m.—Mr Alan D Maclean "Code of Electrical Practice for the Petroleum Industry"

Thursday, May 10

LINNEAN SOCIETY (joint meeting with the ZOOLOGICAL SOCIETY) (at Linnean Society, Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Miss E M Brown and Miss M F Sutton "Observations on the Population of some Emergency Water Supply Tanks, with a Description of the Life-History of *Corixa panzeri* (Hemiptera Heteroptera)", Dr R S de Ropp "Plant Tissue Culture, its Application in Botanical Research", Mr I H Burkill "Flies of the Family Empididae and Other Insect-Visitors to the Flowers of *Tamus communis*", Mr A L Poole "An Indigenous Induced *Phormium tenax* Forest Swamp in New Zealand"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Annual General Meeting

Friday, May 11

ROYAL ASTRONOMICAL SOCIETY (Burlington House, Piccadilly, London, W 1), at 4.30 p.m.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Sir Lawrence Bragg, F.R.S. "X-Ray Analysis—Past, Present and Future"

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the HYDRAULICS GROUP and the MANUFACTURE GROUP) (at Storey's Gate, St James's Park, London, S W 1), at 5.30 p.m.—Mr F H Towler "The Modern Direct-Hydraulic System"

Saturday, May 12

INSTITUTION OF THE RUBBER INDUSTRY (MIDLAND SECTION) (Imperial Hotel, Birmingham), at 10 a.m. and 2 p.m.—Symposium on "The Physical and Chemical Breakdown of Rubber"

INSTITUTE OF PHYSICS (SOUTH WALES BRANCH) (in the Physics Department, University College, Cathays Park, Cardiff), at 2.30 p.m.—Prof W V Mayneord "The Use of Infra-Red Radiation in Medicine"

INSTITUTION OF MECHANICAL ENGINEERS (GRADUATE SECTION) (at Storey's Gate, St James's Park, London, S W 1), at 3.30 p.m.—Annual General Meeting Mr Peter Masefield "The Developments in the Design of Military Aircraft between 1918 and 1944"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

SENIOR LECTURER IN MATHEMATICS—The Principal, Royal Holloway College, Englefield Green, Surrey (May 8)

WORKS MANAGER to control works in Surrey engaged on PRECISION INSTRUMENT PRODUCTION—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2 (quoting C 2562 XA) (May 8)

CONSULTANT TO TIMBER RESEARCH LABORATORY, Transvaal Chamber of Mines, Johannesburg—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting F 3959 XA) (May 10)

TEACHER IN BIOLOGY—The Director of Education, Polytechnic, 309 Regent Street, London, W 1 (May 10)

AN ENTOMOLOGIST (Reference No F 3966 A) and a BOTANIST (Reference No F 3965 A) for the Government of Iraq—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, Kingsway, London, W C 2 (quoting the appropriate Reference No) (May 11)

TEACHERS OF MATHEMATICS, of ENGINEERING SUBJECTS and HANDICRAFT AND DRAWING, at the Luton Technical College—The Director of Education, Shire Hall, Bedford (May 11)

TEACHER OF MINING SUBJECTS at Doncaster Technical College The Chief Education Officer, Education Offices, Doncaster (May 11)

ASSISTANT IN ADVISORY ECONOMIC SECTION (AGRICULTURAL) Leeds—The Registrar, University, Leeds (May 14)

LECTURER IN MECHANICAL ENGINEERING at Norwich City College The Director of Education, City Hall, Norwich (May 14)

PRINCIPAL OF LISBURN TECHNICAL SCHOOL—The Secretary, Cas Chambers, Lisburn, Co Antrim (May 14)

TEACHER OF CHEMISTRY, with special knowledge of Physical and Inorganic Chemistry, at Lancaster Technical College—The Division of Education Officer, Education Office, High Street House, Lancaster (May 16)

DEMONSTRATOR IN PHYSIOLOGY—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women (May 1)

LECTURER IN SOCIOLOGY at the South-West Essex Technical College—The Chief Education Officer, County Offices, Chelmsford (May 1)

PRINCIPAL OF DARWEN TECHNICAL SCHOOL—The Education Officer, Darwen, Lancs (May 31)

ENGINEER TO THE CLYDE NAVIGATION TRUST—The General Manager and Secretary, Clyde Navigation Trust, 16 Robertson Street, Glasgow C 2 (marked "Engineer") (May 31)

ASSISTANT LECTURER and also LECTURER IN GEOGRAPHY—The Secretary, University, Birmingham 3 (June 2)

DIRECTOR OF THE ROWETT RESEARCH INSTITUTE—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (June 18)

LECTURER IN SOCIAL ANTHROPOLOGY—The Secretary, University of Edinburgh (Sept 30)

ASSISTANT LIBRARIAN—The Secretary, University, Aberdeen

LECTURER IN BACTERIOLOGY—The Principal, Studey Agriculture College

RESEARCH STAFF—The Director of Research, British Cotton Industry Research Association, Shirley Institute, Didsbury, Manchester, 20

LECTURER IN MINING at St Helens Municipal Technical College The Director of Education, Education Office, St Helens, Lancs

TEACHER OF ENGINEERING at the Crewe Technical College—The Director of Education, County Education Offices, City Road, Chester

ASSISTANT IN THE CIVIL AND MECHANICAL ENGINEERING DEPARTMENT, in the Portsmouth Municipal College—The Chief Education Officer

LECTURER IN EDUCATION, with special qualifications in the method of teaching Science—The Secretary, University, Birmingham, 3

LECTURER IN BIOLOGY at Stockwell College, Bromley—The Principal, temporarily at Watcombe Park, St Marychurch, Torquay

LOOKING FORWARD

THE announcement of the official cessation of hostilities with Germany overshadows all other considerations. As we have been frequently reminded, we are by no means at the end of our perilous journey, but we can at least rejoice soberly in the accomplishment of one stage of it, and that a stage which has been fraught with the direst danger. When we look back over the past six years, no one can but be amazed at the achievements of peace-loving peoples against an enemy who over a period of years devoted himself to preparations for war.

Much of our success has been due to the efforts of scientific and other professional workers, who were swift to respond to the call for their services. Throwing aside their normal occupations—in industry, the universities and elsewhere—even before the outbreak of war they put themselves individually at the disposal of the country. Through the Central Register, a most valuable body of information on the scientific and engineering man-power resources of Britain was voluntarily compiled, which has made possible the staffing of the large number of war-time factories necessitated by the scale and diversity of needs of modern war. Moreover, the general public has not been unaware of, or ungrateful for, the contributions made by science to the task of defeating the enemy, indeed, there have been times when it has been necessary to check public enthusiasm and to remind people at large that science alone could not achieve a decision. In the Press and in addresses in the Houses of Parliament and elsewhere, there have been many sincere tributes to the effectiveness of the application of scientific knowledge and methods in the most unexpected fields. The reason for this outburst of enthusiasm for science is clear enough, but it is a reflexion upon the general scope of education in Britain—and also upon scientific workers for their lack of missionary zeal—that such achievement should apparently come as a surprise to a majority of the people.

It may not be out of place even here to indicate very briefly some of the noteworthy advances in knowledge which have been brought to public notice during the War. Radiolocation and other developments in radio communication immediately come to mind, in spite of the fact that it has not been possible to publish much definite information on the subject. Happily much of the work in this field of electronics has obvious applications for the days of peace. The development of aeronautics, both as regards power-driven machines and gliders, has been equally striking. Aeroplanes of a size which would have been regarded before the War as possible but highly unlikely within several decades are now almost commonplace, and great fleets of a thousand or more operating as a unit are being used. But beyond great increase in size and speed of the individual machine and of the operational unit, there is a host of ancillary services, each of which can make a contribution to post-war progress. Air navigation, by night and by day, has become as precise as sea

University College
PHYSICS Dept.
Upper Circular Rd, Cork.

navigation, and both will benefit from the increasing sureness of radio communication. The significance of the enhanced power and reliability of internal combustion engines requires no emphasis, and the development of a new prime mover, the jet propulsion engine, though particularly associated in the minds of most people with the 'flying bomb', will have its place in the aerial transportation of the future. Meteorology has been amassing data the importance of which can only be surmised; it is sufficient to note that trans-Atlantic flights in both directions have become matters of routine.

In the medical field there have been equally noteworthy achievements. Turning again to problems connected with the aeroplane, it is noteworthy that much progress has been made in connexion with high-altitude flights. As regards more strictly medical matters, mention must be made of the extended use of the sulpha drugs, and also of the applications of penicillin; between them, there is little doubt that the sulpha drugs and penicillin have been the means of reducing substantially the number of fatalities from war wounds. Great progress has been made, as is usual in such times, in the surgery of war wounds, and also in the treatment of burns. Blood transfusion has been carried out on a scale never previously contemplated, and has led to much important new work on the constitution of the blood, the factors it carries and their significance in inheritance. Considerable importance is also attached to the discovery of new insecticides, of which D D T. is probably best known.

Food technology has also received a great stimulus. The drying of milk and eggs was carried out on a commercial scale before the War, but the cutting off of supplies of fresh eggs from the Continent, and the great curtailment of shipping space, have increased the traffic in the powdered products by an extraordinary amount, until they have become part of our regular rations. Valuable knowledge has also been acquired in the preparation of concentrated foods.

Perhaps more important still is the opportunity which enforced rationing has given of seeing that the nation, as a whole, has had available a diet which medical statistics have shown to be very satisfactory from the point of view of physical health. In this connexion it is interesting to note that, probably for the first time, certain imports have been deliberately regulated as to kind and quantity in accordance with scientific data derived from nutritional studies.

More purely social studies also come into the picture. The paucity of knowledge on population movements and their effects became evident on the outbreak of war, with the ill-conceived but well-executed evacuation of the children of London and other big cities. As a piece of organization the operations were successful, but too little attention was given to the human element, with the result that a steady drift back to the cities quickly set in. The transfer of industries to safer areas was more successful, perhaps of necessity, but brought in its train many difficulties which ought at least have been eased by deeper knowledge of social trends. The data thus painfully acquired will be of

considerable value to future studies of population movements and mass psychology. War-time studies of munition workers and others has also provided useful material in the field of health in industry, and has amply justified the investigations of the Industrial Health Research Board, which originated from similar investigations undertaken during the War of 1914-18.

Enough has probably been said to remind readers that many scientific developments of first-rate importance have taken place during the War. But it must not be imagined that we have any desire to extol war, or even to credit it with additions to knowledge. The developments referred to above were inherent in the progress of science, the War has provided almost unlimited financial support, increased opportunities and the stimulus of public interest born of the nation's peril.

Turning now to the immediate future, and even confining ourselves to strictly utilitarian considerations, there is still a multitude of tasks ahead for scientific workers, from the highest levels to the lowest. In these columns it is not so necessary to stress their part in promoting the well-being of the community, and in industry and commerce, though this is of high importance. We have in mind rather the problem of the control of Germany in the post-war world, and we stress the point because even men of science themselves may not realize the extent to which a just but effective control will depend on scientific knowledge and method. The multitude of problems should be approached in a scientific manner by assembling the data and determining action on the impartial consideration of the whole need not be emphasized. Even in the political field, there are problems of mass psychology on which scientific men should be able to provide valuable guidance. In the control of industry, the influence of the man of science and the engineer is more obvious. Indeed, it is not too much to say that without scientific knowledge it is impossible to devise adequate controls, and policy-making in this field must be largely in the hands of scientific men. Some of the possibilities were indicated in an article in *Nature* of April 24, 1943, p. 455, referring to the control of 'key' chemicals, and reference was made to the difficulty, for example, of effectively separating the fertilizer from the explosives industries.

Then again, adequate control of the manufacture of fine chemicals in Germany will be necessary. Some may go so far as to say that it must be suppressed, but it would be better to ensure that the undoubted abilities of German chemists in this field should be used, not for flooding other nationals' markets to the exclusion of local products and creating world-wide monopolies of strategic and commercial importance, but for the good of mankind. The problem is a difficult one, and should not be dismissed without careful consideration.

Even in the munitions industries it is only the final stages of the products that are specifically connected with war. In their engineering, metallurgical and chemical aspects, they are inextricably mingled with agricultural and other industries. Thorough appreciation of the scientific basis of these

industries is necessary in order to formulate measures control, and more than a superficial acquaintance with physics and chemistry will be required to supervise the controls imposed. Chemical industry should not be entirely suppressed, for that would not only lead to additional unemployment, directly and indirectly, but also to the increased dependence of many on imports, and that at a time when the most strain is being imposed on the United Nations to supply their own needs in the agricultural and industrial fields. Again the problem is an intricate one, which will require careful discussion in the light of all the known facts.

The fact that the Government has been asking for more recruits with various grades of scientific and engineering knowledge for service in Germany after the War in Europe ends indicates that there is appreciation in Government circles of the part that scientific men can play. There can be no question that their services, provided they are not unduly strained by the administrative and military machines, will be of vital importance in the control of Germany.

Enough has probably been said to show that scientific workers have played a full part in the prosecution of the War, and that they must be intimately concerned in the years to come in dealing with numerous problems arising directly out of it. In addition to their *ad hoc* activities, it is generally conceded that science must take an ever-increasing share in the promotion of peace-time industry, and that ample provision must be made for that form of research which is perhaps best described as the pursuit of knowledge for its own sake.

The broad outlines of the strategy and tactics of research in Great-Britain during the years to come are outlined in a series of six articles on "Scientific and Industrial Research" published in *Nature* last month, and the main points are worth repeating. Strategy is the premier consideration, for it must determine the general programme, and it will obviously involve decisions on policy at the highest levels. The whole educational system of the country involved, in that it will decide the quality of the personnel who will carry out research, while the nation must be able to appreciate the significance of the work scientific men do and the way in which they approach their tasks. No rigid dividing line should, indeed can, be set between so-called pure and applied research, and increased facilities should be made available for the interchange of personnel between the universities, industry and Government alike. The recent foundation of senior fellowships in science in the universities, where those appointed will combine research with a certain amount of teaching, is probably a most valuable step in the right direction. This leads inevitably to the consideration of the position of the universities in the post-war world. Expansion there must be, but local innovations would not appear to be needed; universities must continue to be, fundamentally, communities of teachers and students, where knowledge is sought for its own sake, as well as for its use as a preparation for a particular task or mode

of livelihood. In particular, they will be expected to provide opportunities for the development of the qualities required for leadership.

It is, of course, premature to attempt to foresee the optimum number of research workers in advance of the actual programme of research. But some consideration of subjects is not out of place. Thus it is already realized that both biology and geology will require many more trained workers than are at present available, and the universities will have to make corresponding preparations. Social biology is a relatively new and actively growing subject which will demand consideration. Re-allocation of research effort between the various sciences may become an urgent necessity, this will clearly involve machinery for the co-ordination of research in the universities and elsewhere. The British tradition favours evolution, and it is to be expected that existing institutions and methods, where they have proved successful, will be developed and extended. New institutions will obviously be necessary; but flexibility is of prime importance. The increase of State assistance to the universities must not be allowed to encroach on their independence. As regards research in Government institutions, there is at present insufficient correlation of effort between the various bodies, and there should be provision for associating it with advances in the fields of social science and economic science. Research carried out by industrial firms is more difficult to organize, but the suggestion from industry itself of a central co-ordinating office is worth careful consideration.

In any discussion of the future of scientific and industrial research, prominent consideration must be given to the improvement of conditions of service. By this is meant not salary alone, but also questions of status, publication of the results of research, superannuation, interchange of staff between university, Government and industrial institutions, and so on. Here the professional institutions can play a leading part, for they have among their members the varied knowledge and experience which will be invaluable in formulating codes of professional conduct and related matters (see also *Nature*, December 2, 1944, p. 693).

This cursory survey of the present achievement and future significance of science has ended, as it began, with the human element. This has been thought necessary, because it is on the personality, integrity and devotion of the man of science that so much will depend. Never has science stood so high in public esteem, never have the efforts of scientific men been so widely appreciated and acclaimed. Science has been accorded—and willingly accepted—a foremost place in the highest councils of the nations, it must continue in that place, and by its influence justify the faith the peoples have grown to have in it. The key to the present and the future is unremitting vigilance and purposeful activity. There must be no slackening of effort, no relaxation of standards. Rather must the present thanksgiving be a spur to additional exertion, in the sure knowledge that we are building on a tried and stable foundation a new and progressive world order.

MENTAL HEALTH IN WAR-TIME

The War and Mental Health in England

By Prof James M Mackintosh Pp v+91 (New York Commonwealth Fund, London Oxford University Press, 1944) 5s 6d net

THIS book does not pretend to be either a scientific or a medical treatise on the subject of mental health in England during the War. It is a collection of essays written in non-technical language describing the successive phases of the first four years of the second World War and giving an account of the author's impressions of the effect of war conditions upon the population.

It discusses the industrial worker, the new soldier, the housewife, food-rationing, the evacuation scheme and the child in war-time.

There is a general impression that war conditions are unfavourable to mental health and that this is indicated by an increased amount of recognizable mental illness in war-time. The prevalence of neurosis in the War of 1914-18, popularly termed 'shell-shock', and the argument that modern warfare, bristling with new dangers and, in any case, imposing privations of a greater or lesser degree of severity, will exert unaccustomed strain and cause mental breakdowns, are chiefly responsible for this impression.

Examination of the subject shows that the issue is more complex. In the first place, in 1922 the Army Council Committee reported that the name 'shell-shock' should be eliminated, that the War of 1914-18 produced no new nervous disorders but that they were the result of genuine concussion in a small proportion of cases, or the result of emotional shock (usually in constitutionally predisposed persons) in 80 per cent of cases, or the result of nervous and mental exhaustion, and that no psychoneurosis should be classified as a battle casualty any more than sickness or disease is so recorded. Most of the neuroses arising out of the War of 1914-18 were either anxiety states or hysteria. The findings of the Army Committee were fully confirmed at a conference which was held at the Ministry of Pensions in July 1939¹.

In the second place, 'neurotic incapacity', like other forms of disease, is greatly influenced by environment. It is well known that a man infected by tuberculosis—a disease sometimes associated with mental symptoms—may often lead an active and useful life, provided he lives under sheltered conditions and does work adapted to his physical capacity. Put such a man into competition with healthy labour or enlist him into the Fighting Services and he breaks down with his quiescent pulmonary lesion flaring up into activity. In the same way, many a soldier may be diagnosed as mentally ill or be discharged from the Army, who in peace-time would never have come under medical observation for mental aberration, although he may not have been in perfect mental health. As Dr Aubrey Lewis² has observed in discussing this subject:

"So there is in part a spurious rise, due to more systematic medical examination of the population, to more careful diagnosis, and to a change in the demands of the environment, converting a harmless anomaly into an incapacitating disorder. This applies, of course, with especial force to mental deficiency, so-called higher grades—i.e., 'dull and backward', 'feeble-minded'—will be detected and returned in the

statistics of a Service population, whereas they would have escaped attention under pre-war conditions."

It is undoubtedly true, on the other hand, that war brings out qualities of resilience and endurance which make for the preservation of mental health under the most adverse conditions. Before the War certain persons in authority were highly apprehensive of panic and nerve-storms in the congested areas of London when exposed to air-raids. No such disorder occurred. In colloquial language, "the people could take it." The War has inspired a feeling of corporate unity and service to the common weal which help to lessen the incidence of mental illness, and good morale has been shown under the strain of repeated and incessant aerial bombardment.

Another factor for consideration is that in the present War certain reforms have been instituted which are advantageous to mental health. To quote Dr Aubrey Lewis² again:

"If, for example, production committees, welfare managers, and factory medical officers have improved the mental as well as the physical health of workers, they partly counteract the adverse factors in war-time industry, which need no recapitulation. Having been instituted under the pressure of war needs, they may be laid to the credit of war even though the link is not essential."

Lastly, a most important factor is the general improvement in national health which has been secured to a considerable extent, at all events through the national health services, by 1939. This prevented not only physical but much mental disorder.

Dr Aubrey Lewis³ reports that air-raids have not been responsible for any striking increase in neurotic illness, indeed, crude figures from hospitals and outpatient clinics suggest a considerable drop. The incidence of such illness in fire-fighters and other workers in civil defence has been low. Mental disorders in England and Wales have diminished.

In the total number of persons suffering from notified mental disorder there was a decrease of 4,048 during 1941 and a decrease of 3,516 during 1942. The average annual decrease for the five years ended December 31, 1942, was 1,952, which contrasts with an average annual increase of 1,600 in 1934-38 (Twenty-ninth Annual Report of the Board of Control).

Suicides in Great Britain during the war years show a steady drop as contrasted with Germany where, according to the *Reichsgesundheitsblatt* for October 1942, there has been a rise in the suicide-rate in large towns.

The incidence of mental disease and ill-health in the Services has not been large, but there has been a great development of psychological and psychiatric work in these Services, and every endeavour has been made to eliminate misfits and to keep the fighting population both mentally and physically healthy.

Statistical and clinical evidence, on the whole, indicates that war conditions have lessened rather than increased mental illness. It is important to remember that the final chapters of the story have still to be told. "The amount of mental ill-health manifest during the war is not a safe index of what is really happening to the mental health of the community" (Lewis). The figures of the British Ministry of Pensions and those published in the

United States of America⁴ for mental disorders after the War of 1914-18 indicate that a high proportion of men and women affected eventually succumbed to mental illness as a result of prolonged war-strain.

Prof Mackintosh advocates greater attention to psychiatry in the medical curriculum and enhanced encouragement by the State of the psychiatric social worker. The difficulty here is that psychiatry embraces many schools of thought, it is by no means an exact science, and sometimes the patient treated by a fervent disciple of Freud has his mental illness aggravated rather than ameliorated. As Lewis² observes "I do not think we shall need cohorts of psychiatrists". But we do need general practitioners trained on sound lines in the social and psychiatric problems of their work and familiar with the mental aspects of organic disease.

Much mental illness has a physical basis and the converse statement is also true. In this connexion reference may be made to an interesting paper by Morris and Titmuss³, which discusses the rising mortality from peptic ulcer. The authors claim that the effects of heavy air attacks during 1940-41 resulted in, first, a sharp rise in mortality from duodenal ulcer which was closely followed by a similar movement in mortality from gastric ulcer. The circumstances were, at all events, associated. There is a constant interplay between physical and mental ill-health.

Work of this kind opens out fresh avenues of research into the nature of the relation between mental and physical disease, which is a much more hopeful line of investigation than speculative theories concerning repressions, obsessions and complexes.

Prof Mackintosh's book calls for little criticism. He makes too sweeping a statement on p. 7 when he observes that "pre-war Government policy did little to improve physique and nothing to uplift the mind". The work done by the Education and Health Ministries of Great Britain in physical training, in the provision of milk and meals in schools, in preventive medicine and in hygiene over a number of years preceding the War, had greatly improved the physique and nutrition of the school-child in comparison with the past. Nor had the question of the physique of the adolescent been ignored. The Board of Control was pursuing an enlightened policy towards mental disease, and considerable attention was devoted to the neuroses and the treatment of mental defectives. Indeed, Prof Mackintosh's own work both as a medical officer of health and as chief medical officer of the Department of Health for Scotland would alone indicate that pre-war Government was not unmindful of its responsibilities for physical and mental health.

These essays give a vivid historical picture painted in words with considerable literary ability. They emphasize the grit, self-control and determination of the English people when fighting for their national existence and they show how the nation, as a whole, acclaimed and responded to the inspiration of Mr Churchill's leadership. **ARTHUR S. MACNALLY**

POST-WAR NUTRITIONAL RELIEF IN EUROPE

Nutrition and Relief Work

A Handbook for the Guidance of Relief Workers. (Published by the Council of British Societies for Relief Abroad.) Pp. 111. (London, New York and Toronto: Oxford University Press, 1945.) 5s. net.

THE appearance of this little text-book is indeed opportune. Soon there will be at work in many European countries a large army of relief workers, both foreign and native, of whom very few can have had any previous experience of the job they have undertaken. As usual, a good proportion of these workers will be English-speaking, and for these this book in English, with all the relevant information and sound advice contained in its hundred pages, should prove a real companion and guide. The list of experts invited by the Council of British Societies for Relief Abroad to form a committee responsible for this guide book itself gives promise of a worthy production. The result is no disappointment.

The earlier chapters contain a simple but scientific account of the physiology of human nutrition, of the energy or calorie value, and the separate nutritive elements—proteins, fats, carbohydrates, minerals and vitamins—which must be included in an adequate diet, and further of the quantitative requirements for each of these dietary essentials. This is followed by a description in non-technical language of the signs which may indicate a state of partial starvation due to a lack of food in general, as well as of the symptoms which may suggest a specific deficiency of one or other of the essential nutrients, and of the variability of these symptoms as they may appear among different classes of the population—infants, children, and adult men and women. Tables are given which show the calorie value and composition of the chief foods, including their content of minerals and vitamins.

The remainder of the book, devoted chiefly to the technical aspects of nutritional relief, reveals the wide experience possessed by those who have compiled it. Sections are devoted to methods of dietary surveys, to storage and handling of foods, to camp equipment and emergency methods of cooking and serving meals.

A particularly interesting chapter deals with the food habits peculiar to the inhabitants of different European countries, situated, respectively, in the north and west, and south and east, and a useful table is given which shows the consumption of principal foods in these districts in periods both before and during the War. Here perhaps a little criticism of minor points and a few additions might be useful. In Italy, although consumption of other dairy produce may be low, it is the usual custom to take grated cheese with the almost daily meal of macaroni or spaghetti, the widespread use of garlic in cooked foods might also be mentioned. In Austria and some parts of southern Germany, the meat, usually eaten at the midday meal in all but the poorest households, most frequently takes the form of *Rindfleisch*—beef of poor quality which is stewed in the soup which precedes it and is rendered palatable by a variety of sauces, changed from day to day. The glossary of food and cooking terms in French and German might be enlarged with advantage and some alternative expressions given. For example, in South Germany and Austria milk curd is usually
